INDEX

A	Page.
Aamdal copper mines	537
Abrasive, garnet used as an	114
Acid, composition of concentrated sulphuric acid	177
Accident Insurance, employers' liability and, F. J. Martin	380
Accidents and their prevention, mine, Ed. Ryan	859
Mine-owners' liability for	A. J. Pillsbury
Railroad	542, 572, 603, 633, 668
Accurate 'Stop-Coppers'	Editorial
Act for Bureau of Mines, new	A. J. Sale
Adamson, L. F.	287
The year among Nevada mines and mills	75
Adaven Mining & Smelting Co.	905
Adler, Sidney	213
Central American mines in 1911	489
Advance in copper	Editorial
In Silver prices	252, 283
Ditto	265, 363
Adverse claims	114, 848
Advertising out a co-owner	614
Value of plain truth	Editorial
Aerolith apparatus	444
Affairs of the American Institute	Editorial
Afforestation in Korea	Editorial
Africa, copper from Central	Editorial
African diamond mining	67
Plateau, physiography of the East	George L. Collier
Afterthought Copper Co.	420, 483
Agglomeration of fine materials	Walter S. Landis
Agitating and circulating solution	510
Ditto	Courtenay De Kalb
Agreements	444
Agricultural and mineral lands, leasing	Editorial
Ahmeek mine	352
Ahmeek Mining Co.	546, 836, 868
Alasworth	68
Air current, velocity of	414
Discharge pipes and receivers, explosives in	216
Holists, direct	848
Hose, machine-drill	614
In gas-engine cylinder, compressed	284
Measuring low-pressure	G. S. Weymouth
Air-compressors	553
Lubrication	782
Operations	E. A. Rix
Straight-line	581
Alrometer, Excelsior	Excelsior Drill & Mfg. Co
Ajax-Clancy process mill	80
Ajax Gold Mining Co.	487
Ajax mine	168
Alamos district, Sonora, Mexico	G. L. Sheldon
Old mines at	278
Alaska and its needs	Editorial
And the Yukon	Guy A. R. Lewington
At Washington	Editorial
Be Developed? How can	H. Foster Bain
Ditto	Anthony Elfrer
Ditto	Julius Thompson
Continental type of glacial deposits in	Lawrence Martin
Copper mines	Editorial
District, gold deposits of Sitka	Adolph Knopf
Government railroads in	Editorial
Governor's report	Editorial
Home rule for	Editorial
Immediate needs	96
Legislation of Alaska and the Yukon	Guy A. R. Lewington
Matanuska Valley coalfields	G. C. Martin and F. J. Katz
Mining at Treadwell	863
Mining in 1911	A. H. Brooks
Needs, Alaskans on	666
New placer districts	A. H. Brooks
Rich gold-quartz mines of	Editorial
Sweepstakes all	Editorial
Timber in	282
Tin-dredging	Lydia R. Clements
Ditto	T. M. Gibson
Trails	Editorial
Alaska Mexican Gold M. Co.	119, 419, 457, 675, 761, 807, 863, 867
Alaska Dredging Co.	46
Alaska-Ehner Gold Mines Co.	547
Alaska Mexican Gold M. Co.	119, 449, 547, 675, 761, 807, 863, 865
Mill record	861
Mine	353
Ore reservoir	863
Alaska Treadwell Gold M. Co.	119, 353, 387, 483, 608
Mill flow-sheet	761, 771, 903
Mine	38
Alaska United Gold M. Co.	119, 353, 419, 517, 675, 761, 807
Ore reserves	863
Returns	861
Alaskan development	Julius Thompson
Mining laws, proposed revision of	F. Lynwood Garrison
Railway building	Editorial
Alaskans on Alaska's needs	666
Albert Theodore, death of	908
Alby Carbide Co.	511
Allee mine	470
Allee Mining Co.	872
All-Alaska sweepstakes	521, 517
Allen A. W.	Estimation of tonnage
Ditto	Laboratory cyanide tests
Ditto	Mill and cyanide plant records
Ditto	Pebble efficiency in tube-milling
Ditto	Possibilities of British Papua

Ditto	Statement of construction costs	702
Ditto	Statement of working costs	204
Ditto	Tonnage estimation	541
Allen, Irving C., and George Burrell	Liquid products from natural gas	436
Allys-Chalmers Co.	Editorial	555
Allshar mine	Editorial	556
Alloys, zinc-aluminum	Editorial	759
Alpha Consolidated M. Co.	Editorial	184
Alpha mines	Editorial	384
Alpine Quicksilver M. Co.	Editorial	11
Alta Bert Gold Dredging Co.	Editorial	290
Alta Consolidated Mining Co.	Editorial	115
Alta Tunnel & Transportation Co.	Editorial	115
Aluminum	Editorial	177, 781
Ditto	Editorial	651
Alloys, zinc	Editorial	759
Improving	Editorial	177
Alundum plates, filtration with	Editorial	206
Alunite near Marysville, Utah	B. S. Butler and Hoyt S. Gale	210
Alvarado Mining & Milling Co.	Editorial	293
Report	Editorial	811
Amador county, California, immigrant gold-mine work-	W. J. Lauck	279
Amalgamated Copper Co.	479, 545, 546, 635, 770, 835	842
Report	Editorial	707
Amalgamated Development Co.	Editorial	605
Amalgamated Pioche merger	Editorial	411, 627, 706
Amalgamated Zinc Co., Ltd.	Editorial	382
Amazon River	Editorial	342
Amendment act of New Zealand, mining	Editorial	705
Amendments to placer-mining act, Dawson, recent	Editorial	765
American and foreign technical journals	'Noah's Ark,' T. T. Read	159
Iron trade	Editorial	17
Mines	Editorial	526, 564, 592
Mining act, birth of—I, II, III	H. W. MacFarren	718
Mining and land laws, need of revision of	Editorial	556
Mining law	Editorial	367
Mining law, failure of	Editorial	129
Museum of Safety	Editorial	316
Rosin sold in Japan	Editorial	265
Steel rails	Editorial	890
Sulphur trade	Albertus Koch	819
American Copper Producers' Association, statistics	Editorial	225
American Flag mine	Editorial	131
American Institute affairs	Editorial	251, 543
American Institute of Mining Engineers	Editorial	266, 329, 330, 817
Ditto	Editorial	249
Annual meeting of	Editorial	248, 302
New York meeting	Editorial	298
Ditto	Our special correspondent	344
Iron and steel division of the	Editorial	699
Spokane section	Editorial	805
American Metallurgical Society, San Francisco chapter	Editorial	420
American Mining Congress	Editorial	355, 486, 540
Ditto	Editorial	395, 585
Montana chapter	Editorial	905
American Agricultural Chemical Co.-Tennessee Copper	Editorial	804
Co., proposed merger	Editorial	577
American Oroville Co.	Editorial	472
American Rutile Co.	Editorial	849
American Smelters Securities Co.	Editorial	86, 293, 449
American Smelting & Refining Co.	Company reports	520
Ditto	Editorial	730
Dividends	Editorial	487
Earnings	Editorial	678
Foreign laborers' strike	Editorial	876
In Mexico	Editorial	487
Smelter at Aguascalientes	Editorial	875
Spokane offices	Editorial	129
American Society of Engineering Contractors	Editorial	804
American Telegraph & Telephone Co.	Editorial	391
American Tungsten 'Con. Corporation	Editorial	180
American Zinc, Lead & Smelting Co.	Editorial	421
American Zinc Ore Separating Co.	Editorial	193
Amparo Mining Co.	Editorial	91
Mine	Editorial	793
Work of the	Editorial	470
Anur region, gold-dredging in the	Editorial	363
Anaconda, Montana, farmers versus smelter at	Editorial	177
Anaconda-Butte-Ballaklava settlement	Editorial	822
Anaconda Copper Mining Co.	83, 121, 157, 219, 291, 545, 546, 671, 685, 770, 813	265
Ditto	Company reports	870
Ditto	Editorial	480
Annual statement of	Editorial	152
Washoe smelter of the	Editorial	714
Anaconda Gold Mining & Refining Co.	Editorial	695
Anaconda Mining Co.	Editorial	285
Anadir Mining Co.	Editorial	478
Analyzed Hollinger report	Editorial	212
Ancient river beds in California	Editorial	802
Andaray-Posco mine	Editorial	413
Anderson, Charles E.	Editorial	482
Angels camp, Lightner mill	Editorial	121
Anglo-Continental shares, slump in	Editorial	55
Antelope mining district	Editorial	212
Anthracite coal shipments	Editorial	881
Antimonial lead	Editorial	478
Tailing, cyanidation of	W. Archer Longbottom	55
Anthony	Editorial	171
In Italy	Editorial	7
Arkansas diamond-bearing peridotite areas	Editorial	
Appelbaum, Misha E.	Copper, corporations, and prices

L. A. GREENE - - - - - Business Manager
Entered at San Francisco Postoffice as Second-Class Matter.

Greeting!

The close of one year and beginning of another is universally a time for casting up accounts. The merchant takes stock, balances his books, and decides what lines to push in the new year. In solemn family council father and mother add up the bills and debate measures necessary to stretch a fixed income to cover an expanding style of living. Everywhere people are sifting and sorting to determine, if possible, what is, and what is not, worth while. I ask your indulgence for a few minutes that we may have a conference of the *Mining and Scientific Press* family, including the publishers, editors, readers, and advertisers, to consider ways and means.

Changes come even in the most united of families. Children grow up and move away, and from time to time new faces appear at the fireside. In 1911 pressure of other business has prevented a number of our friends from keeping up the relation of special contributor, and several have accordingly dropped out, though we hope not for always. Their writings have contributed greatly to the interest of the paper, and their future articles, if unfortunately less frequent, will be no less welcome. When 'business lets up', or any of them reach that haven to which every mining engineer looks forward when he shall live on a ranch and bother only with cattle and alfalfa—a cordial reception awaits his reëntly into our circle of those who by frequent note and advice help to shape the paper. Other old friends remain in the list and to them the thanks of the editor, swelled, I am sure, by those of the readers, go today. As newcomers we have welcomed Mr. T. Lane Carter, who has written for us frequently

this year of South Africa, Central America, and other countries; Mr. Charles Janin, who is keeping in especially close touch with the development of gold-dredging; and Mr. A. W. Allen, whose knowledge of South America and many other countries will be generously placed at the disposal of our readers. Mr. Courtenay De Kalb has found life in Mexico too exacting for frequent editorial contributions, but continues as a special contributor. Mr. T. A. Rickard, having placed *The Mining Magazine* upon a satisfactory basis as to clientele and business, will find time this year to devote to the *Mining and Scientific Press*. With an eye to rivaling our New York contemporary, *The Outlook*, Mr. Rickard is accordingly listed as Editorial Contributor, and our readers may expect in 1912 a series of those delightful essays and articles for which he is famous.

In the year that has just closed the advertisers have given generous support to the paper; support all the more liberal in that business has undeniably been less good than in 1910, and only the far-seeing business men recognize that it is in bad times that good firms prove their quality and by extra efforts lay the foundation for rapid expansion in the first succeeding period of prosperity. The readers have been kind and discriminating. Many cheering words have come from them to the editorial office, and if there have also been complaints, who shall say that they were not, in part at least, well founded? On behalf of the editors I can say we have given the best we had. If you have missed an expected news item, if you have failed to find a bit of technical information for which you were searching, I can only say that we selected from the store available, to the best of our judgment, what would surest serve your needs. If something has been crowded out, I would remind you that the field is wide and printing forms are not elastic. The Business Manager remarks, too, from his seat in the far corner of the room, that paper and printing bills have steadily climbed while subscription and advertising rates have remained fixed. Extra pages cost extra money, and, pleasant as it is to publish 'the largest paper,' there are limits that must be respected. We have done what we could in 1911 and we shall hope to do better in 1912. The practical problem is, how? And the only reasonable answer is, through the help of our friends. Not that our friends have not already proved more than kind. In the course of the past year members of the editorial staff have visited many States of the Union and a number of foreign countries, and have everywhere been the recipients of much appreciated courtesies. Whether with fellow members of the Institution of Mining and Metallurgy in London glasses clinked over the 'rare roast beef of old England'; or at Colorado Springs, for one brief space of time among the millionaires, as coffee and cigars went round, the story of Cripple Creek was retold; or with fellow travelers at Chitina we ate ham and eggs for breakfast, varying the fare by taking eggs and ham at luncheon, and ham for dinner; or with new-found friends at the Maple Club in Tokyo we gingerly sampled grilled *tai* and *sake*, everywhere it has been the same story of cordial welcome, of quick sympathy, and of ready helpfulness. The year, for myself and associates, is stored full with pleasant memories. Day after day, too, in San Francisco, where a new chair in a new office welcomes old friends to the sanctum, there has been a stream of royal good fellows from all over the world giving of the fullness of their experience and knowledge through the editor to their fellows in the profession.

Service is necessarily the keynote of a technical journal. If it does not serve, and serve well, it withers and dies. And service depends upon knowledge, and knowledge upon willing friends. Give us then of your friendship and your knowledge, that we may give to others. Did it

ever occur to you, Mr. Mine Owner, that there would be substantial advantage in allowing us to publish the real figures at which you bought that last property? The promoter, of course, hies himself joyously to the local printshop, gathering in a few ciphers on the way, and the local editor, with the laudible ambition to 'boost' his own community in announcing the sale, perhaps plants a few more where they will do the most good. The next time you try to buy a property you find, as a result, that prices have 'unaccountably' risen. We have known many a good trade to fall through because of honest but none the less absurd notions of the present value of a property acquired by claim-owners through this sort of education. Mr. Sidney Jennings is quoted as saying that for his company he looked into 601 properties and was able to buy only two; yet the United States Smelting, Refining & Mining Company has an enviable reputation for fairness in examining and buying properties. A Dutch mining engineer of knowledge and personal wealth spent some months in the United States and Canada in 1910 and 1911, with a view to acquiring a property or properties. He was prepared to pay a fair price, and he was careful and thorough, but he went back to Holland without buying, and has turned his attention to the Far East. There are whole districts in California and other States where no new capital is going into mining, and the residents wonder why. In part, the reason lies in the crudities of our mining laws, whereby every purchase or find of a good orebody involves a lawsuit, but in part this stagnation is due to the exaggerated notions of claim-owners as to the value of their properties. This is not true in the States alone, for quartz-mining in the Philippines is making but slow progress, and the most important single reason is, that men with money can not buy claims at fair prices. A million dollars in the ground is not worth a check for a million in the bank, and better education in present values is needed.

And you, Mr. Engineer—do you remember the time when, isolated and lonely, far from professional associates and engineering libraries, you awaited the coming of each number of your favorite technical journal, knowing that it alone stood between you and the rustiness that leads to failure? Have you ever, in making estimates, wished you knew exactly what a certain other plant had cost? Have you ever, in puzzling over a process, wished you knew exactly how the other fellow did it? Do you realize that such information can only be obtained by free interchange—that you can not expect to receive unless you also give? Does not such generous publication of detail as in the series of articles on the Goldfield Consolidated mill by Mr. J. W. Hutchinson, published in this journal last year, or the painstaking and exact tables of cost presented in this issue through the courtesy of Mr. G. M. Taylor, call for some return on your part? Such articles require more of labor and effort than any publisher can pay for in money, and the only fitting reward is like generous publication by those who reap the benefit. Engineers must help each other, and it is one of the pleasures of belonging to the profession that the obligation is so widely recognized. It is true, undoubtedly, that there are times and circumstances under which metallurgical secrets must be kept. The experience of Mr. Richard S. Pearce at Argo with the Pearce process, and that of Mr. Willard S. Morse in converting copper matte at Aguascalientes, may be cited as cases in point, to mention only such as have passed into history. Too often, however, the manager who guards jealously 'a method all his own', has merely failed to measure the depth of his own ignorance. So surely does this policy of secrecy defeat its own ends, that many instances might be cited. One in the experience of one of the larger metallurgical companies will do. The manager at

one of the plants of this company went through an expensive and disastrous campaign that might have been avoided had he had the information available at another property belonging to the same company. Everyone has seen mines repeatedly examined at large expense, has seen processes repeatedly tried without result, and has seen time and money wasted where a little frank interchange of information would have been of the greatest benefit. There is reason in all things, but it is hard to be patient with the absurd lengths to which the policy of secrecy leads some engineers and managers. Government bureaus, engineering societies, technical publications, all the recognized means of building up your profession and business, gentlemen, depend on you. They are what you make them. No editor can give out what is not given to him, and if you would have better papers, give them better and more complete data. For the generous support that you, both readers and advertisers, have given the *Mining and Scientific Press* in 1911, I thank you for myself and on behalf of my associates, and for 1912 I bespeak your continued sympathy and support, at the same time that I wish for you all, the fullest measure of prosperity. From the Nizina to Rancagua, from Moji to the Aneobra, from San Francisco to Kalgoorlie, on to London and back again to the "Golden City in the Golden State by the Golden Gate". I send the good wishes of myself and associates to the many mining engineers we have come to look on as personal friends.

H. FOSTER BAIN.

January 1, 1912.

REGULAR departments have been ruthlessly crowded aside to make room this week for review articles, and even much matter pertaining to a first of the year issue has been regretfully held over.

METALLURGICAL development at Cripple Creek is so associated with the name of Argall, that it is pleasant to be able to present a summary of progress for the year prepared by Mr. P. H. Argall, who is now carrying on work initiated by his father, Mr. Philip Argall, so well known to our readers.

TO CYANIDE operators, one of the events to be looked forward to at the beginning of each year is the appearance of the annual review of progress in cyanidation by Mr. Alfred James. 'Good wine needs no bush,' and we need only mention, therefore, that Mr. James' summary appears on another page of this issue.

JAPAN and the Japanese have won many friends among American engineers in the past year, and, since the New Year is a period of which much is made in the Land of the Rising Sun—not one but three celebrations being held there—we are glad to send to our neighbors across the Pacific our especially good wishes at this time.

STATISTICS of production in 1911 are given this week as far as they are available. The excellent preliminary estimates furnished annually by the Director of the Mint, the Director of the United States Geological Survey, and the monthly figures of the Copper Producers' Association and similar organizations, permit a comprehensive summary of business at the close of the year that is extremely helpful. Estimates are not expected to be exact, though those mentioned have enviable reputations in that particular. Readers will notice a few discrepancies. For this reason the source of the figures has been given in each case. In addition, we gratefully acknowledge the assistance of the many friends whose cooperation has made possible the preparation of this review number.

NEVADA'S enviable record in 1911 has attracted wide attention. The excellent general review of mining in that State which we publish this week was prepared by Mr. L. F. Adamson, State License and Bullion Tax Agent, whose position as collector of the State's share of mining profits, enables him to speak with exceptional knowledge.

CONTROVERSY between German producers and American consumers of potash salts has been finally settled, and an agreement reached which, though causing a loss to the American interests, is apparently satisfactory. One undoubtedly good result of the disagreement has been the stimulation of search for sources of supply on the American continent, though so far little definite result has eventuated.

DENVER is fortunate in containing within its purlieus the Colorado Scientific Society, whose meetings have been notable, since they were the gathering place of notable men. The Society continues with unabated vigor and we note that Mr. G. E. Collins will be president for the coming year, with Messrs. E. N. Hawkins and W. P. J. Dinsmore as vice-presidents, J. W. Richards as treasurer, and H. C. Parmelee as secretary. We wish the Society long life and continued success.

MINING LAW revision has attracted much attention recently, both in the United States and Canada. It seems likely that in 1912 active steps will be taken toward a comprehensive rewriting of the statutes relating to mines. We plan to treat the matter in some detail in an early issue, and are glad to present now the discussion by Mr. F. Lynwood Garrison of the problems in Alaska and of Dr. James Douglas of the cost of developing coal on public lands. Such articles strike bottom and such information is a prerequisite to any informed discussion.

WHEREVER mining men go, to the uttermost end of the earth, the name of Collins is known and respected, worthy sons having upheld the traditions of an honorable sire. Mr. H. F. Collins has prepared for us a valuable discussion of the conditions under which mining is carried on in Spain, which will be of interest as well as service to our readers. Americans are becoming a cosmopolitan people, and this is especially true of mining engineers, so that reviews of mining in Turkey, Japan, and other countries which also appear in this issue, will be of value.

COPPER smelting is likely to remain an important factor in the production of the metal, since it is the most expensive one and shares with ore dressing the honor of having made notable advances in recent years. In connection with the review of progress for the year, by one of the editors, it is interesting to note that the oil-fired reverberatory furnaces constructed at El Paso, Texas, under the direction of Mr. Willard S. Morse, were built with 100-foot hearths, but provision was made for the addition of 20 feet more, which, in the light of experience at that and other plants, is likely to be added.

DREDGING has become a most important means of gold production, and the method is being applied to tin in an increasing number of places. In 1910 dredging operations supplied \$9,293,100 of the \$96,269,100 of gold won in the United States, and the proportion is steadily increasing. We print this week especially interesting articles descriptive of dredging operations, written by Mr. T. M. Gibson, Mr. Hennen Jennings, and Mr. Charles Janin. A continuation of Mr. Janin's review of dredging operations throughout the world will be printed next week. Mr. Jennings' brief description of winter work in Montana will, we are sure, be read with especial interest.

PETROLEUM producers found 1911 an anxious year, but one of substantial progress. The California fields are discussed in detail by Mr. J. H. G. Wolf in this issue, and the general situation on the Pacific Coast was outlined in an earlier issue by Mr. M. L. Requa. Evidently an adequate supply of fuel oil has been developed to warrant steam users changing from coal to oil throughout a wide field. Producers must seek consolation for low prices in this broad market, but one wonders what would happen if the United States Government should insist upon capping wells upon disputed ground until controversies as to title were settled. Evidently the present low prices are by no means certain to prevail, and probably producers may expect better returns in the future. A slight increase in price at the well would benefit them without seriously handicapping consumers, and in view of the risks and capital involved, such an increase is warranted. In the Appalachian fields the price of crude oil was raised late in December, but it is more and more evident that better prices can do but little to increase output east of the Mississippi. According to the *Oil City Derrick*, the new production of the Appalachian fields for the first eleven months of 1911 was 23,649 bbl., as against 49,208 in 1910. The Lima field has practically been abandoned, new production being but 5689 bbl. In Illinois, according to figures compiled by Mr. R. S. Blatchley, of the State Geological Survey, the 1911 output was 31,000,000 bbl.; a marked decline, due to exhaustion of early found pools and lack of development. Prices were raised at intervals through the year and some of the newer fields offer distinct promise, though there is no immediate hope of discoveries rivaling those of 1905 and 1906 in Eastern Illinois. In Oklahoma, Texas, Louisiana, and other Western States, aside from California, the year passed without marked incident. In Mexico production is now estimated at 200,000 bbl. per day.

GENEROSITY has always characterized the miner, but at the end of the year a new and striking instance of this trait was exhibited in the announcement that Mr. F. G. Cottrell and his associates had presented to the Smithsonian Institution the patents covering electrical precipitation of suspended matter. The Cottrell process has already been described in this paper. It is in successful operation in California in acid works, cement manufacturies, and for clearing crude oil of water. Extensive experiments in treatment of smelter fume indicate that it has here a wide field, and further work is now being conducted in Utah. Royalties have, we are glad to say, reimbursed Mr. Cottrell and his friends for the large sum of money spent in developing the process. In the ordinary course of events they might have been expected to result in a considerable fortune. Mr. Cottrell, however, does not care for a business life, and desiring to devote his time to further experimental work under the service of the Bureau of Mines, wished to divorce himself from any private interest in the results of his public work. His associates in San Francisco, with a broadmindedness that is as pleasant as it is unusual, consented to join him in the gift, reserving only the already developed California field. We understand that Mr. Cottrell's example has already been taken to heart by other inventors, so that it is not unlikely that in time the Institution that has done so much for the advancement of scientific research in the world may be fully endowed as a result of that advance. The choice of a depository for the patents is a wise one, since the Smithsonian, while under the protection of the Government, is legally a private corporation and can handle such matters in the same business-like way as could any company. It is thus assured that the patents will neither be buried nor pirated, and much good is certain to result from the gift.

The Year Among the Gold Mines

The close of a year affords convenient opportunity for comparisons between the estimated production for the year just completed and the official figures for the preceding year, since both become available at about the same time. In the case of gold it is useful to compare these with the production of five years earlier, in order that we may obtain a series of 'cross-sections' of the industry which may prove of service in its study. The table below gives the official figures of gold production for the principal gold-producing areas of the world for 1905 and 1910, to which is appended an approximate estimate of the yield during 1911. It should be noted that the data for 1911 for the United States, and the world's production for 1905, 1910, and 1911 are the figures of the Director of the United States Mint, since considerable differences exist between statistics prepared by different authorities. Nevertheless useful conclusions can be deduced. It would appear that the output of gold is no longer increasing at so rapid a rate as formerly, since the increase 1905-1910 was approximately 20 per cent, while the increase in 1911 over 1910 was only 2½ per cent. It is also obvious that practically all the increase is due to African production, since the out-

GOLD PRODUCTION OF THE WORLD

	1905.	1910.	1911.
Africa, Transvaal.....	\$101,225,558	\$155,730,260	\$170,000,000
Rhodesia	7,203,865	12,607,791	12,000,000
West Coast....	3,427,995	3,674,087	5,500,000
Madagascar ..	1,369,553	2,149,721
United States (total) ..	88,180,700	96,055,200	96,233,528
Alaska	14,925,600	16,987,990	16,002,976
Australasia (total)...	85,970,779	65,329,705	59,000,000
Western Australia....	40,490,000	30,393,000	29,800,000
World's production....	377,647,700	454,000,000	466,000,000

put of the United States, which increased slightly during the five-year period, is now almost stationary, while Australasia has been declining slowly but regularly, the decline being general, though it will be noted that during the past year Western Australia has exhibited a tendency to hold its own. Africa, on the other hand, shows a general advance, with the exception of Rhodesia. But even in the case of the Transvaal the rate of increase appears to be slackening, for it will be noted that the increase for 1905-1910 was nearly 53.5 per cent, while the increase during 1911 was 9.6 per cent. It would seem, therefore, in the absence of unexpected changes in the status of the industry, that a period of declining world's output lies in the not remote future. It is unnecessary to attempt at this time to further analyze the gold production of the world, since we hope, early in the year, when fuller statistics are available, to be able to present a more complete discussion of the topic by Mr. T. A. Rickard.

Turning to the United States production, of which a fuller analysis appears upon another page, we find that California has, during the year just past, taken first place, so long held by Colorado. Nevada remains in the third place, pressing Colorado closely, and Alaska has fourth place, which it assumed in 1910, dropping from second in 1909. It is a curious fact that the four leading producers range from twenty to sixteen millions of dollars each, while the next nearest State, South Dakota, produced only about seven and a half millions. Utah, Montana, Arizona, and Idaho complete the list of the States which produced over one million dollars each.

Comparisons are always of interest, and it may be worth while, therefore, to add that the greatest gold mine in the world, from the standpoint of tonnage, is the Randfontein Central, which hoisted 217,984 tons and milled 212,510 tons

during October 1911. The greatest dividend payer of the year was the Goldfield Consolidated, which declared dividends for the year amounting to over \$7,000,000, having milled approximately 338,000 tons of ore of a gross value of over \$10,600,000. The largest dividend payer of the year on the Rand was the Crown Mines, which had declared dividends amounting to £517,058 for the ten months ended in October. The largest mine in America from the tonnage standpoint is the Homestake, which milled over 1,500,000 tons in 1911, though this is almost equaled by the Alaska Treadwell mines, which milled 1,500,000 tons. The competition between these two companies is very close, and it is not unlikely that their relative positions may alter at any time. The Treadwell mines have 900 stamps at work, with a stamp duty of over 5 tons per day, and at the Homestake the 1000 stamps have a duty of a little over 4.2 tons per day. The daily output of the Treadwell mines is therefore slightly greater, but working conditions permit the Homestake to operate more continuously, thus overcoming the handicap. The deepest gold mine of the world is the Morro Velho, in Brazil, owned by the St. John del Rey Mining Company, though the deeper mines along the Mother Lode in California are worthy companions, the Kennedy, which is the deepest gold mine in America, having attained a depth of 3550 feet. The United States takes, therefore, no mean place in the gold industry, being second in total production, having the largest dividend payer, and having more dredges at work than all the rest of the world combined.

Mexico Regains Stability

The year 1911 has been one of disturbed conditions in Mexico, and the mining industry has suffered as a result. The Madero revolution, just gathering force a year ago, triumphed within a period of six months, overthrowing a government that had proved strong for more than a quarter of a century. Labor troubles and brigandage have followed in the wake of the political upheaval, and attempts to overthrow the Madero government were for a time feared. Failure late in the year of the counter-revolution attempted by Gen. Bernardo Reyes has set these fears at rest. Francisco I. Madero was legally elected president in October, taking charge of Mexico's affairs on November 6, ending a provisional government of five months' duration. At present the prospects for a peaceful administration are better than at any time in the year. When consideration is given the great political changes wrought by the Madero revolution, it becomes a matter of wonder that the mining industry of the country has not suffered to a much greater extent than it has. In many of the important mining districts of Mexico the political upheaval had practically no effect on operations, and production has been well maintained throughout the year. Naturally, little foreign capital has entered the country during the year, and few important transactions have been recorded; money for projected extensions and betterments has been lacking, and few new enterprises have been launched. An exception, and one that illustrates the faith in the future of the country held by those who know it best, was the continued investment of money throughout the period of disturbance by the men associated with the American Smelting & Refining Company.

The hostilities of the revolution were principally confined to the States of Chihuahua, Sonora, Durango, and Coahuila, and in these mining, milling, and smelting suffered serious interruptions. In northern Mexico railroad lines were cut early in the year, and some of them remained out of commission until after peace was declared. Toward the end of the revolution the affected railroad

lines totaled several thousand kilometres. Early in the revolution the Diaz government prohibited the transportation of dynamite with the object of keeping the explosive out of the hands of the revolutionists, and later the damage to railroads made its transportation impossible. Mining companies that were not well stocked with dynamite were eventually forced to curtail or suspend operations. For some time the Mexican Express Company, operating on the National Railways of Mexico, refused to assume any responsibility for the handling of bullion and money.

The labor troubles that followed the political upheaval in Mexico were mostly of short duration. Strikes have occurred at the Torreon, Mapimi, Chihuahua, Asareo, San Luis Potosi, and Matehuala smelters, and in a number of mining districts, including Velardeña, El Oro, Santa Eulalia, Cananea, and Nacozari. In Chihuahua, when the smelter workmen were ready to return to work they found that the management had no intention of immediately reopening the smelter, and the plant remained closed for several months. During the revolution Mexican workmen generally gained the impression that the triumph of Madero would mean shorter hours and higher pay. Some are now voicing a demand that Madero take steps to bring this about.

Railroad construction in Mexico during 1911 has been limited. The Pearson extension of the Mexico Northwestern railway in Chihuahua was delayed by the revolution and will be completed late this year. Since the close of the revolution the company has built a 22-kilometre branch into the Cusihiuriachie silver-mining district. The revolution also delayed construction of the Durango-Cañitas line of the National Railways, which will provide transportation facilities for the Sombrerete, Nieves, Chalchihuites, Nombre de Dios, and other mining districts. The work out of Cañitas was suspended, and is only now being resumed. The Southern Pacific has just completed its West Coast extension to the Tepic capital, and late in the year engineers of the same company were sent into the field to make surveys for a projected line from Guadalajara to Mexico City. There has been no interruption of work on the Penjamo-Ajuno line of the National Railways, building through the State of Michoacan, and good progress has been made in the building of the Pachuca-Zimapan line, in the State of Hidalgo. An electric line has been built to connect the big Pachuca and Real del Monte districts in Hidalgo. The Mexican Union Company, owning the Torres and Prietas line in Sonora, has been building an extension to Ures.

These advances in railway construction and development are especially worth emphasizing, in that they indicate a substantial recovery from the disturbed conditions naturally incident to a period of revolution. In another column our Mexican correspondent reviews at length the mining situation at the close of the year. The picture he presents is no less cheerful, and it is accurate. The ways of our southern neighbors are not our ways, and a presidential change there is accomplished through methods that differ from our own. It is a debatable question whether their methods result in more real loss to business than follows our own prolonged agitation for a new president and a revised tariff. There are times when the direct methods of the revolutionist at least appeal to one. Mexico has had a troublous year, but has come through it without much damage and with a basis for much permanent gain. It is too much to expect that all troubles are over, but we are not among those who see only clouds in the future, and we are glad to congratulate Mexico and the Mexicans upon the excellent prospects with which they enter 1912.

Review of Metal Production in the United States in 1911

Gold and Silver

The deposits of gold bullion at the mints and assay offices of the United States by domestic producers and domestic refineries during the calendar year 1911 amount approximately to 5,808,982 fine ounces, of the value of \$120,082,315. This compares with 5,826,104 fine ounces, of the value of \$120,436,258 from the same sources in 1910. These figures include bullion extracted or refined in this country from imported ores, but indicate that the gold

when it rose rapidly to the high point of November 21. At the close of the year the price was practically the same as a year ago. The price of silver is intimately related to crop and political conditions in the Far East, modified by the manipulations of a keen lot of speculators at Bombay. Higher prices late in the year seem to have been due to the trouble in China, but more silver is now being shipped from London than a year ago, and with good crop conditions in India higher prices may be expected.

*Value 54c. per ounce.

production of North America was practically the same in 1911 as in 1910. In the table above are given the gold and silver production of the United States in 1910, revised figures furnished by the U. S. Geological Survey being used, and preliminary estimates for 1911, published by the courtesy of George E. Roberts, Director of the Mint. The 1911 figures do not show complete distribution.

It will be noted that silver production in 1911 is estimated at 57,796,117 oz., as compared with 57,137,900. From Mexico, which is the leading silver producer of the world, the exports in 1911 were substantially the same as 1910, but the production, owing to disturbed political conditions in the northern States, was undoubtedly less than in 1910, when it amounted to 72,574,220 oz. The Canadian output was larger than in 1910, when it was 31,983,328, by some 3,090,000 oz., due mainly to the larger amount of low-grade ore treated at Cobalt.

The price of silver, as shown by the weekly quotations, has ranged from 51.80 to 56.40 in cents per ounce, New York. Starting above 54c., the price dropped to the low point by the middle of February, and then remained fairly steady until the second week in October,

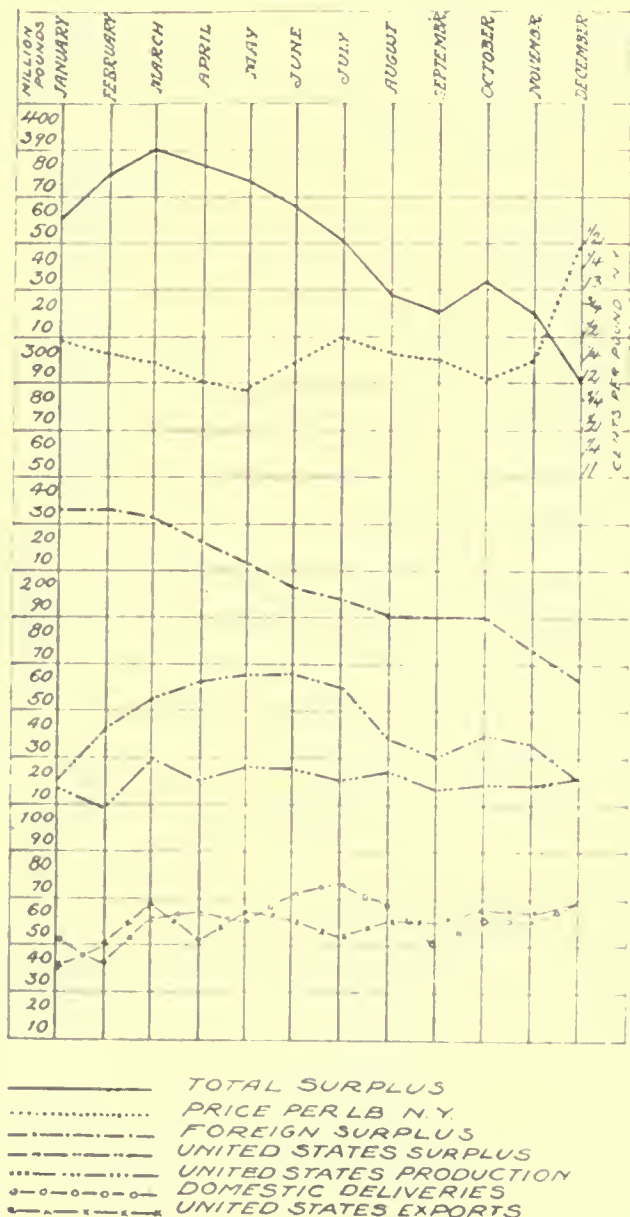

Copper

Statistics and estimates received by the U. S. Geological Survey from all plants known to produce blister copper from domestic ores and from all Lake mines indicate that the copper output from the United States in 1911 exceeded that of 1910 and nearly equaled the record production of 1909. The figures showing smelter production from domestic ore, which have been collected by B. S. Butler, of the Survey, represent the actual production of each company for eleven months and include an estimate of the December output. The November figures for a few companies were not available and these companies furnished estimates for the last two months of the year. According to the statistics and estimates received, the output of blister and Lake copper was 1,091,554,000 lb., against 1,080,159,509 lb. in 1910 and 1,092,951,624 lb. in 1909. Arizona again holds first place, followed in order by Montana, Michigan, Utah, Nevada, California, Alaska, Tennessee, Colorado, Idaho, and New Mexico. Monthly figures of production and consumption, and the course of prices through the year, are described in another column by Mr. Appelbaum.

Copper, Corporations, and Prices

By MISHA E. APPELBAUM

Fluctuations in production, price, and surplus of copper in 1911 are shown graphically in the accompanying diagram, which is based on the figures of the Copper Producers' Association and the New York quotations published weekly in the *Mining and Scientific Press*. During the first ten months of 1911 the price of copper fluctuated within narrow limits, and the steady tone of the market was principally due to the enormous consumption abroad

COPPER IN 1911.

and to fairly normal consumption in this country. Toward the end of the year, due principally to the small production, a large buying movement developed in Europe. At first American consumers had little faith in this movement and did not enter the market until the price had passed 13c. As a result, however, of liberal purchases on their part, the market quickly advanced, and at the present writing is very firm at 14c. per lb. The statistics for the year show that consumption has more than overtaken production, and as another 25,000,000 lb. decrease in surplus is expected during December, the figures on the first of January should show the visible supply to be less than at any time since the beginning of 1907.

As usual, when the metal experiences a violent advance in price, there are numerous predictions of a copper fam-

ine, and, on the other hand, there are people who have no faith in the advance, claiming that the statistics are padded, that the exports are not legitimate, etc. It has been absolutely proved, however, that each copper producer sends to the Producers' Association, on the first of each month, an actual statement of the metal at his refinery. The Producers' figures have checked with those of the Government, and there seems no reason for questioning their accuracy. It is difficult to know upon what basis the charge is made that the copper exported does not go into real consumption. Certainly the visible supply in Europe shows a steady decrease, in spite of the enormous exports. I, for one, do not believe that with the present business conditions, or even allowing the moderate improvement, which is the most that can be expected during a Presidential year, there can be a copper famine. It is quite true that the visible supply is small, and that, should anything happen to one of the leading mines, the metal might advance very quickly. A particularly sudden business revival might also bring about a sharp increase in price, but, assuming that neither of the two will occur during the coming year, I think that the metal will fluctuate between 13½ and 15c., instead of, as during the former few years, between 12 and 13½c. Assuming that the production of copper during the coming year from the old mines remain on the same basis as during 1911, there will be enough copper produced by the few new mines to take care of a moderate increase in consumption, and, furthermore, if the metal should advance to a higher level than 15c., a larger production on the part of existing mines would immediately prevent a runaway market.

There is a good deal of talk to the effect that an agreement should be made among the producers to fix a minimum and maximum price for copper. I fail to see how any business man understanding economic conditions can advocate this. I believe that once a departure is made from the universal rule that prices should be governed by the law of supply and demand, it will create an artificial condition, and, while this might temporarily bring about a better tone to copper, it would eventually result in a much more demoralized condition than can possibly occur if everything is left to the law of supply and demand. The great trouble with business conditions is that, while the need of proper and conservative laws is admitted by everyone, much worse cures are proposed than present methods involve. I fully concur with the opinion of some of the leading business men, that unnecessary competition is ruinous, but I, for one, do not believe that to eliminate competition almost entirely, will be beneficial. The resources of this country having grown to an enormous volume, it is but natural that this growth should bring on many difficult problems, but in solving them, and in passing laws to cope with the enormous combinations, no departure should be made from the universally established principles that competition is the life of trade, and that prices should be governed by the laws of supply and demand. For this reason, I do not see any necessity for creating a large copper combination or having any agreements among the producers as to prices. The best evidence, to my mind, that such agreements are not necessary, is, that the metal during periods of depression has sold around 11c. per lb., and that, without any agreements or laws as to the minimum and maximum price, it at other times advanced to 26½c., because the demand was greater than the supply. Simply because this country has for the past few years been through a period of depression and readjustment, and has registered low metal prices, does not mean that in periods of activity we shall not again see prices very profitable to the producer. If, in the meantime, the wheel of fortune runs in favor of the consumer, this should not be begrudged. Furthermore, this has its advantage that the low copper prices have stimulated consumption and that an enormous surplus is being gradually worked off.

As to the probable course of prices for 1912, it is extremely difficult to predict. The majority of people believe that during a period of tariff readjustment and political

agitation incident to a Presidential election, it is impossible to expect brisk business. Some believe that business will be extremely poor, but I am inclined to hold that the year of 1912 will be at least a little better than 1911, though brisk business cannot be expected until the Presidential election has been settled, and a conservative but wise policy on the part of the Government toward business interests has been established. By that, I do not mean that the Government should shut its eyes to any wrongdoing on the part of corporations; neither do I mean that it should go out of its way to file complaints against those that are known to have lived up to the letter of the law. From my point of view, it is ridiculous for a government to file a dissolution suit against a corporation simply because administrative officers believe that in some particular it has not lived up to the letter of the law. If the rank and file of the people engaged in the same business as competitors admit that the tactics of such corporation have been fair, reasonable, and just, it seems to me that the corporation should be encouraged rather than harassed. The result of the dissolution suit against the United States Steel Corporation will, I think, mark the beginning of a new era in this country, for I believe that the United States Supreme Court will come to the conclusion that the only fault to be found with that corporation is in its tremendous size and the volume of business it is doing, and that the Sherman law was never intended to limit an individual or a corporation provided its work were directed with proper business methods. The corporation question is much in the same state as the tariff question. If it is admitted on all sides that a tariff board composed of the leading business men and statesmen is more able to cope with the question than politicians, I do not see why a corporation board, composed of the leading business men and statesmen should not also be able to handle the question more intelligently. This, with a compulsory Federal incorporation law, would give the board proper supervision over interstate business, and, with a broad viewpoint, it would be able to solve most intricate questions without any disturbance in business.

Zinc Ore and Zinc Smelting

By R. G. HALL

The condition of the zinc business in the year just closing presents a remarkable contrast with that prevailing for some years previously. The latter months of 1910 foreshadowed more prosperous times for the smelter, and as the year 1911 advanced, the smelting margin grew greater. When the conditions which prevailed in the business from the close of 1907 until well into 1910 are considered, no one can deny that the people who have invested money in zinc smelters are entitled to some sunshine between the periods of cloudy weather. Notwithstanding the efforts of the Joplin Ore Producers' Association, the law of supply and demand has not yet been repealed. In the boom days of gas production in Kansas, when a plant could be supplied with fuel by a well in its own yard, gas apparently cost very little. To embark in the smelting business was accordingly an inviting undertaking. The inevitable result was the building to a greater smelting capacity than was justified, either by the supply of ore or the demand for spelter. The shortage of ore was met by importations from Mexico and British Columbia, until the Payne tariff bill put on a prohibitory duty. The resulting decrease in the smelter's margin, together with the rapid decline in the Kansas gas supply, put many gas plants out of existence, while the increasing price of ore stimulated production from the mines. All this tended to work in favor of the smelter. At the beginning of 1911 the reported stocks of metal in producers' hands were about 23,000 tons, which was shown to have diminished to about 17,000 tons by the middle of the year.

European conditions were also such as to bring about high prices, and during the third quarter of the year the prices in the two countries were such as to make it profitable

occasionally to export domestic metal. As our own supply was also short, the result was a rapid advance in the domestic price, until in November it, for a time, reached \$6.85. St. Louis, with some sales reported at even higher figures. From that high point the price tumbled almost during one day, to around \$6.20, at which point it has held pretty steadily. The year closed with stocks in the hands of producers unusually low, and in the hands of consumers down to such a point as they have probably never reached before in recent years. The available statistics of ore production are complete only for the Missouri-Kansas and the Wisconsin districts. They are given below.

APPROXIMATE TONNAGE, ALL ORES OF ZINC

Missouri-Kansas district, 1911	270,000
Wisconsin district, 1911	76,000
	346,000

PRICES IN THE MISSOURI-KANSAS DISTRICT

Month.	Base price 60% blende.
January	\$41.85
February	40.21
March	39.85
April	38.88
May	38.25
June	40.50
July	40.75
August	42.50
September	42.63
October	42.38
November	45.40

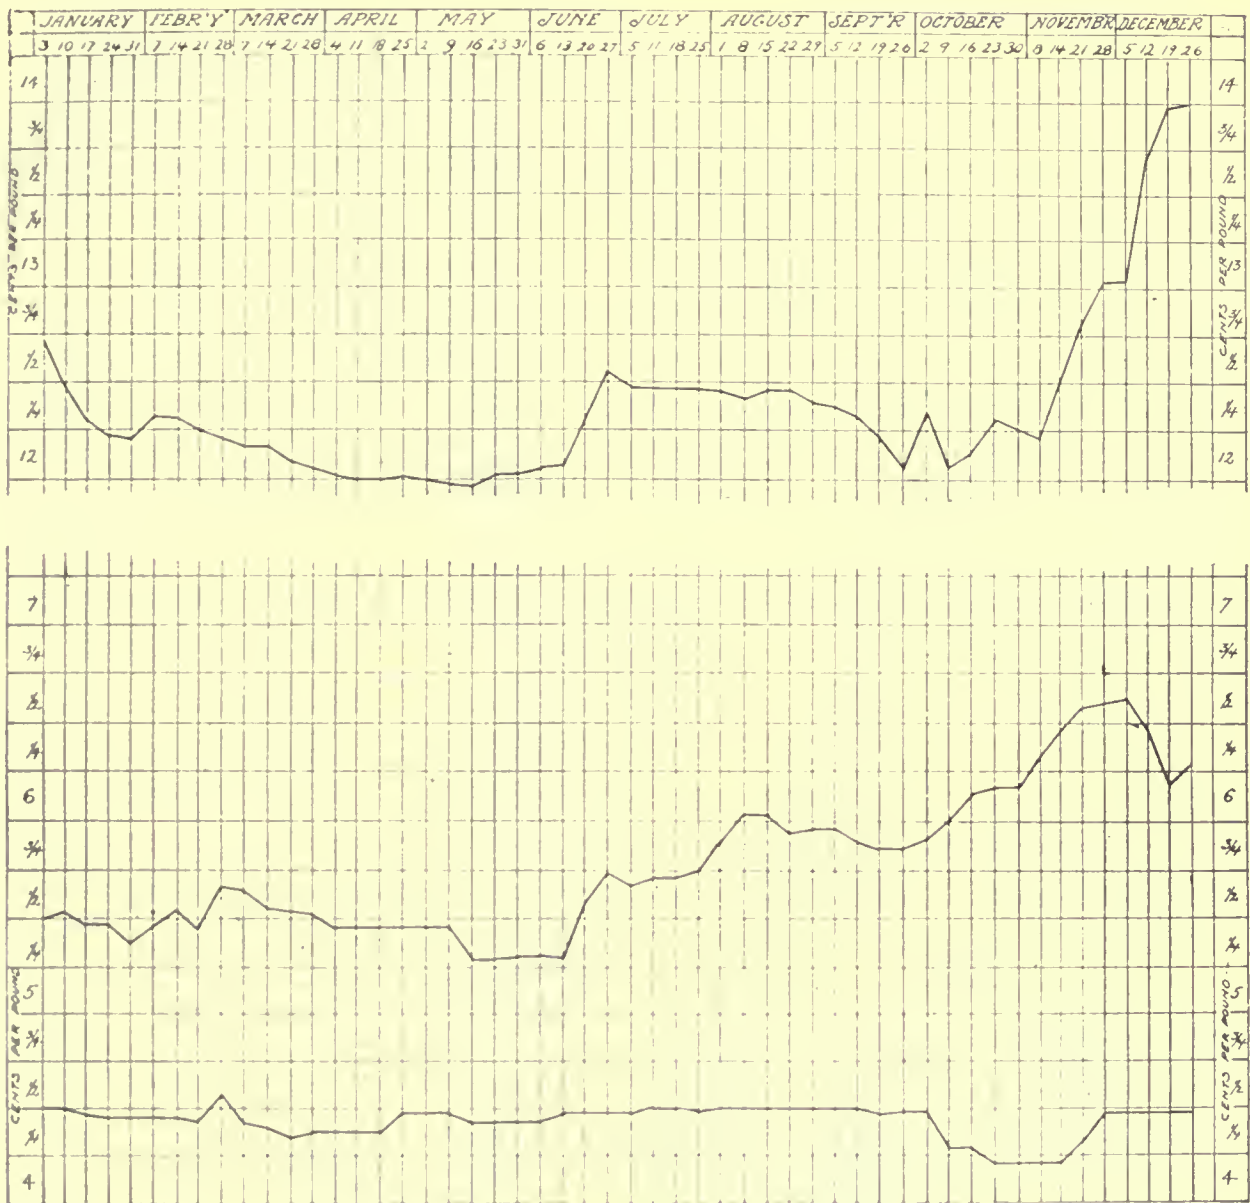

The production in 1910 was 269,000 tons for the Missouri-Kansas district and 56,000 for the Wisconsin district. The prices paid in the two years show, for 1910 an average of \$40.42, and 1911 an average of \$41.20 for the first eleven months. Apparently the Missouri-Kansas district has made no increase in production, notwithstanding an increase in price, while the Wisconsin output has shown a gratifying advance; perhaps because the mine operators in Wisconsin devoted more time to the mining of ores than they did to attempts to control the market.

In the Western orefields the most interesting development has been the greatly increased production of carbonate at Leadville. The end of the year finds that district with a daily production of close to 350 tons. The tonnage of sulphide ore from Leadville has probably not increased materially, while in the other parts of the State no noteworthy new properties have been opened. Montana's production was large. Fire recently stopped production at the Clark properties, but the Butte & Superior mine continues to operate, and ships a large tonnage. The year 1912 will probably record interesting developments here. The new concentrator of the Butte & Superior company is nearly completed, and W. A. Clark is said to be contemplating building a new mill to replace the one recently destroyed. In Idaho the Success mine has made regular shipments, the Morning mine has begun making some production of zinc, and the Black Horse has been added to the list of producers. In Nevada the Good Spring district continues a good production of carbonates. Other production from the Rocky Mountain States will show a material advance over 1910, and the outlook for ore from these States in 1912 is bright.

The average spelter prices for 1911, at St. Louis, are given below. New York prices, shown in the diagram and quoted from week to week in the *Mining and Scientific Press*, are normally 15c. per hundred higher. At rare intervals there is a wider margin, but when it occurs it is promptly closed.

January	\$5.60	July	\$5.79
February	5.70	August	6.04
March	5.67	September	6.03
April	5.51	October	6.24
May	5.52	November	6.63
June	5.62	December (Est.)	6.25

Considerable new smelting construction was under way

LEAD, ZINC, AND COPPER PRICES IN 1911.

in 1911. In Oklahoma the Bartlesville Zinc Co., owned by the American Metal Co., is constructing a plant of 5 blocks, or 3200 retorts, and the Tulsa Fuel & Mfg. Co., of the New Jersey Zinc Co., has about completed one of 7 blocks, or 4680 retorts, all at Collinsville. These plants are both partly completed and operating, and will be producing at full capacity in the early months of the new year. In Illinois the R. Lanyon Zinc & Acid Co., owned by William Lanyon, has under construction an acid works and two blocks, or 1600 retorts. This will be completed early in 1912. The American Zinc, Lead & Smelting Co. is constructing an acid works and a 5-block plant of 4000 retorts.

LIST OF PLANTS UNDER CONSTRUCTION

American Z. L. & S. Co.	Hillsboro, Ill.	4000
Bartlesville Z. Co.	Collinsville, Okla.	3200
R. Lanyon Z. & A. Co.	Hillsboro, Ill.	1600
Tulsa F. & M. Co.	Collinsville, Okla.	4680

No new developments are to be recorded in zinc metal lurgy for the year in the United States. Some spelter is being produced in Norway by electric furnaces and much experimenting has been done with this method of smelting. In California, especially, important work is being conducted by the Bully Hill Copper M. & S. Co. Undoubtedly some developments along this line may be looked for in the future, but to date nothing of importance has taken place in this country, and for the present attention is being concentrated on better ore dressing and improvements in the

conduct of smelting by standard methods.

ZINC SMELTING PLANTS IN OPERATION

Lead and Zinc Mining

The U. S. Geological Survey has prepared a preliminary statement of the lead and zinc mining industry in 1911. This statement is compiled by C. E. Siebenthal from the most reliable sources available at this time. It appears probable that the mine production of domestic lead in ore in 1911 made a gain of between 25,000 and 30,000 tons over the 395,313 tons produced in 1910, which, when compared with the estimated increase in the smelter production of domestic lead, 35,987 tons, indicates that domestic lead-ore stocks at the smelters were considerably depleted during the year. This is emphasized by the fact that a large stock of lead ore was accumulated at a Western lead smelter now under construction. Of the great lead-producing districts, that in southeastern Missouri is believed to have fallen behind 1910 by about 4%, while Idaho gained 15% in output. The Joplin district yielded 45,500 tons of lead concentrate, Utah gained about 8%, Colorado remained stationary, and Nevada fell behind about 9%. Montana and Arizona showed large gains.

It is believed that the mine production of recoverable zinc in ore was about 20,000 tons greater than the output of 327,712 tons in 1910. The increase in the output of domestic spelter in 1911 was apparently 21,328 tons. The quantity of zinc recovered as zinc pigments is not known at this time, so that conclusions as to zinc-ore stocks cannot be drawn. The production of the Joplin and Wisconsin districts is discussed elsewhere by Mr. Hall. New Jersey made its usual production, Tennessee attracted much attention and made substantial gains. Leadville is estimated to have shipped 80,000 tons of 30% zinc ore. Montana gained about 40%, as did also Idaho. Nevada increased its output about 60%, while Utah fell behind.

Spelter

Estimates made by C. E. Siebenthal of the U. S. Geological Survey covering production and consumption of spelter in the United States in 1910, show that the year was a record-breaker in many particulars. Both production and exports exceeded those of any previous year.

The production of spelter from domestic ore is estimated at 273,807 short tons, and from foreign ore at 14,237 tons, a total of 288,044 tons, worth, at the average price, \$33,837,000, as compared to a total of 269,184 tons in 1910, made up of 252,479 tons of domestic origin and 16,705 tons of foreign origin. The production of spelter from both domestic and foreign ores, apportioned according to the States in which smelted, was approximately as follows: Illinois, 84,626 tons in 1911, as compared to 73,038 tons in 1910; Kansas, 97,790 tons in 1911, as compared to 105,697 tons in 1910; Oklahoma, 46,061 tons in 1911, as compared to 34,760 tons in 1910; all other States, 59,587 tons in 1911, as compared to 55,689 tons in 1910. The total production of spelter is equivalent to the output of 67,555 average retorts operating continuously through the year, or about 80% of the effective smelting capacity of the country when working 60% zinc concentrate.

The apparent domestic consumption of spelter in 1911 may be computed as follows: The stock on hand at smelters at the beginning of the year, 23,232 tons, plus the imports, 285 tons, and the production, 288,044 tons, gives the total available supply of 311,561 tons. From this there are to be subtracted the exports of domestic spelter, 5,292 tons, the exports of foreign spelter, 10,678 tons, the exports under draw-back, 2628 tons, and the stock on hand at smelters December 15, 9023 tons, a total of 27,623 tons, leaving a balance of 283,938 tons as the apparent domestic consumption. This calculation takes no account of the stocks of spelter held by dealers or consumers. On comparing the consumption in 1911 with the 245,884 tons consumed in 1910, the 270,730 tons in 1909, the 214,167 tons in 1908, and the 226,969 tons in 1907, it is to be noted that the apparent consumption is abnormally large, indicating that stocks other than those at smelters have appreciated.

Lead

The total production of refined lead, desilverized and soft, from domestic and foreign ores in 1911 was approximately 487,520 short tons, worth at the average New York price \$43,876,800, compared to a production of 470,380 tons in 1910 and 448,112 tons in 1909, according to figures compiled by C. E. Siebenthal of the U. S. Geological Survey. These figures do not include an estimated output of 13,195 tons of antimonial lead, against 14,069 tons in 1910 and 12,896 tons in 1909. Of the total production, desilverized lead of domestic origin, exclusive of desilverized soft lead, is estimated at 208,428 tons, against 193,213 tons in 1910; and desilverized lead of foreign origin at 89,706 tons, compared to 108,553 tons in 1910. The production of soft lead from Mississippi Valley ores is estimated at 189,386 tons, compared to 169,244 tons in 1910, which means that Missouri retains first place among the lead-producing States. The final figures for the production of soft lead in 1911 are likely to show an increase of a thousand tons or so over those above given because the argentiferous-lead smelters and refineries undoubtedly treated more or less soft-lead ore from the Mississippi Valley which is not taken into account in their preliminary estimates.

The amount of lead available for consumption during 1911 may be estimated by adding the stock of foreign lead in bonded warehouses at the beginning of the year, 35,972 short tons, the imports, 91,244 tons, and the domestic production, 397,814 tons, making an apparent supply of 525,030 tons. From this is to be subtracted the foreign lead exported from warehouse, 103,656 tons, the exports of foreign lead in manufactures under draw-back, estimated at 10,468 tons, the deduction by liquidation, 16,178 tons, and the stock in bonded warehouses at the close of the year (assumed to be the same as at the close of November), 3728 tons, leaving as available for consumption 391,000 tons, which by comparison with 376,021 tons in 1910 and 370,013 tons in 1909 seems to be a normal increase.

The foreign lead remaining in warehouse at the close of November 1911 was distributed principally as follows: At Chicago, 630 short tons, compared with 10,545 tons at the close of 1910; at Newark, 975 tons, against 3774 tons at the end of 1910; at Perth Amboy, 125 tons in 1911 and 18,056 tons in 1910; and at Paso del Norte, 1852 tons compared with 3469 tons at the close of the preceding year.

Mr. Siebenthal's figures are of especial interest in that they furnish the only information available as to surplus and stocks. Sales of lead in the United States are largely in the hands of the Guggenheim interests, and in that connection the curve of price for lead in 1911 may be compared with interest with that for spelter, in which there is here a free market. The two curves show the effect of 'stabilizing' an industry. The price of desilverized lead was even steadier than indicated by the graph. On October 5 it was reduced from 4.50 to 4.35, that being the first reduction in price since November 18, 1910. October 15 it was dropped again to \$4.25. Current quotations take into account the soft lead of the Mississippi Valley which now dominates the situation.

Tungsten

There was a sharp falling off in the production of tungsten ores in 1911, owing to the decrease in the market for tool steels, in which the bulk of the tungsten is used. According to preliminary figures collected by Frank L. Hess, of the United States Geological Survey, about 1125 short tons of concentrate carrying 60% tungsten trioxide was produced and shipped during the year, which is less than two-thirds of the output for 1910, when 1821 tons was marketed. The prices for the year ranged from \$4.50 to \$8.50 per unit, depending on quantity, quality, and individual bargaining. At the close of the year \$5 per unit was offered. The unit is twenty pounds of tungsten trioxide per short ton of ore.

As usual the Boulder County (Colorado) fields gave the

largest returns, 740 tons, and the Atolia (California) deposits the second largest. Smaller amounts were produced in Arizona. Near Nipton, California, work was done by several persons on tungsten-bearing veins, but most of the ore was left at the mines to await higher prices. New mills for treating tungsten ores were operated at Osceola, Nevada, and in the Blue Wing district on Patterson creek, Idaho, and a new mill was being built at the close of the year at Round Mountain, Nevada.

Tin Mines and Market

The year 1911 was characterized by great irregularities in the London tin market, as noted by Mr. Rickard on another page. These sudden gyrations of the market were duly reflected in New York with certain added permutations. Late in the year tin advanced in London to £205, equivalent to 44½¢. per lb. At the same time it was announced from the Straits that shipments the first half of December amounted to 3354 tons, and for the month they were estimated at 5500 tons. This brought the total for the year up to 54,870 tons, which is a small increase over last year instead of a decrease as anticipated. According to L. Vogelstein & Co., English and Continental deliveries for eleven months averaged the same as in 1910 and in the United States were slightly less. Figuring on this basis for December, total deliveries for the month should run 600 or 800 tons in excess of supplies, and the visible supply December 31 should have been about 16,000 tons, or 1000 tons less than a year ago. This shows a very even balance between supply and demand. Consumption has really exceeded production, more than these figures indicate. The excess has been drawn from invisible supplies and non-statistical brands, principally Bolivian. Visible supplies frequently and for long periods have been at much lower figures, and present high prices are predicated, not so much on the present situation as on the fear that in the early months of 1912, after the Chinese New Year, Straits shipments will fall off and a serious depletion of stocks occur. Meanwhile supplies will pile up in London.

Average monthly quotations at New York in cents per pound are given below:

	1910.	1911.		1910.	1911.
January	32.70	41.255	July	32.69	42.40
February	32.92	41.614	August	33.97	43.32
March	32.40	40.157	September	34.98	39.75
April	32.98	42.185	October	36.19	41.18
May	33.12	43.115	November	36.55	42.12
June	32.77	44.606	December	38.20	45.90

Of more interest is the commencement of actual shipments of tin from Alaska, as noted by Mr. Gibson, the record of actual shipments from the Black Hills, and the development of our new sources of supply in various parts of the world, as recorded by Mr. Rickard. In the Transvaal tin excited some interest and shows promise, but it cannot be said that its progress has come up to expectation, nor has the long anticipated 'boom' made its appearance. The value of the tin-ore shipments commenced to increase in January, when it was £12,508, and continued to steadily increase until May, when it reached £48,938, but fell to £22,867 in September. There are, however, only two important producing mines in the Waterberg district, which fact will go a long way in explaining the variation in shipments. The Waterberg tinfield has come into increasing prominence during the year, and quite a large number of properties have been taken up by companies, syndicates, and others. The tin ore occurs in both lodes and 'pipes,' the latter being sometimes described as 'chimneys.' They vary considerably in shape, occurrence, and tin content. Quite an extensive area has been proved to be mineralized, and one mine the Zaaiplaats—has for some time paid dividends at the rate of 200% per annum, the 5s. shares standing in the market in the neighborhood of 90s. As before remarked, a tin boom has been looked for throughout the year, but up to the time of writing it was still out of sight. Near Victoria, in Rhodesia, tin discoveries were announced, and created some stir, but development indicates that the deposits are patchy and irregular.

Quicksilver

The year 1911 was important to American producers of quicksilver mainly because of changes in selling conditions. As is well known, the major part of the American output has been marketed for some years through a single selling agency known as a 'trust' and which worked in close harmony with the Rothschilds in London. In February last, one of the leading producers withdrew his account, and, being followed shortly after by others, the combination was quickly broken. Today buying and selling of quicksilver is on a strictly commission basis and the market is one of the freest in the metal trades. San Francisco is the primary American market for quicksilver, though quotations there, as furnished weekly in the *Mining and Scientific Press*, show a relation to those in New York not greatly different from that obtaining between St. Louis and New York prices for lead. There is also a relation, though not as close as formerly, between New York and London prices. At times this year New York quotations have been as much as \$3 above the London parity, though without importations. The average quotation by months in dollars per flask of 70 lb. each, is given below:

	1910.	1911.		1910.	1911.
January	50.87	44.60	August	46.75	50.00

Production in 1911 was probably a little below that in 1910, but prospects for 1912 are unusually good. California, which remains the main producing State, shipped 17,211 flasks in 1910, a trifle over 18,000 in 1911, and will probably ship 20,000 in 1912. Texas, which ranks second, shipped 3320 flasks in 1910, but only about 2500 in 1911, and probably will not ship more in 1912. It is

ALPINE QUICKSILVER FURNACE.

not that the Texas mines are failing, but that the market in St. Louis, which is the one principally supplied from Texas, does not require more, and the producers do better not to scramble for general business. Nevada and Oregon each produce small amounts. Probably 100 flasks would cover their output in 1911. Nevada, however, will soon become a more important producer, as the Mercury Mining Co. is building a furnace at Lone and should ship early in 1912. In California the New Guadalupe M. Co., New Idria M. Co., Quicksilver M. Co., Oceanic Quicksilver Co., and the Helena mine remain the principal producers. There are in addition a considerable number of small furnaces. The Alpine Quicksilver M. Co. operates a 5-ton Scott furnace, as shown above, near New Idria. The ore is the usual cinnabar in a crushed serpentine, and is said to exist in considerable quantity and up to 7% in grade. Plans are under way for increasing the capacity of the plant. A number of other properties have attracted attention in the past year, and the outlook is distinctly favorable for increased production.

Operation of Air-Compressors

By E. A. Rix

An air-compressor is rated by the displacement of its piston or pistons in single-stage machines, and by its low-pressure piston in two-stage or multi-stage machines. It is self-evident that this is the proper manner, although it is theoretical. Any attempt to give the actual delivery of an air-compressor would give the consideration of many factors, quite difficult to ascertain. It is right, however, for the public to know about this, for when an air-compressor seems unable to do its work or was not large enough in the first place, an intelligent idea of its deficiencies may be helpful in providing a remedy. While an air-compressor does not differ materially from a steam-engine in matters that affect its volumetric efficiency, a steam-engine which is delivering its horse-power is only criticized for its economy, while a compressor, whether economical or not, if it does not deliver the volume, is not doing its work and may therefore have to be replaced. It may be helpful to inquire into the principal things that affect volumetric efficiency, and perhaps among some of them an explanation may be found for the failure of any particular machine under consideration. Inasmuch as single-stage compressors constitute the majority of all air-compressors operated, these may be considered first, and inasmuch as the majority of air-compressors are built for and operated under 100-lb. air-pressure, investigations will be directed to that pressure. The factors affecting the volumetric efficiency are: (1) Piston and valve-pocket clearance; (2) piston and piston-rod leakage; (3) valve leakage and slip; (4) temperature; (5) piston speed.

Piston and Valve-Pocket Clearance.—When the displacement of a compressor is given in terms of the volume swept by the piston, it supposes that there is no clearance of any kind in the cylinder, and that all the air in the cylinder is forced into the receiver. This, however, cannot be done in practice, for the piston must not reach either cylinder-head by a reasonable distance demanded for safety in operation, and this varies with the character of the compressor. Few builders leave less than $\frac{1}{16}$ in., and many $\frac{1}{4}$; an average may be safely taken as $\frac{1}{8}$ inch.

When compressing air to a given receiver pressure, it always takes a higher pressure within the cylinder than is indicated in the air-receiver; this is due to the power required to force the air through the valve passages. At 100-lb. receiver pressure, the pressure remaining in the clearance space is at least 5 lb. greater, or 105 lb., which corresponds to eight atmospheres or eight compressions. The $\frac{1}{8}$ in. of clearance, then, is filled with air at 105-lb. pressure. Now, when the piston begins its intake stroke it is evident that, until the compressed air in the clearance space expands to atmospheric pressure, no air can come in from the atmosphere. An eighth of an inch clearance would thus hold compressed air enough at 105 lb. to expand to one inch before any air came into the cylinder. In other words, the stroke has been actually shortened one inch. It is evident, therefore, that the shorter the stroke with the same clearance, the less the volumetric efficiency; a 16-in. stroke losing 6%, an 8-in. stroke losing 12%, and a 4-in. stroke 24%. It might not be supposed that anyone would operate a 4-in. stroke machine with any such clearance as $\frac{1}{8}$ in., but I have seen a 4-in. gasket put under the heads of a 4-in. stroke compressor that already had $\frac{1}{16}$ -in. clearance, making $\frac{3}{16}$ -in. clearance; and this simply because a gasket of that size was on hand. It was therefore used, the result being that the compressor doctor had to be called in.

Now, in addition to the piston clearance, there are the pockets below the outlet and inlet valves that add to the other clearance. Generally speaking, this is about one-fourth of the piston clearance. Taking both these clearances into consideration and reducing them to percentage of cylinder volume, it may be said that the average single-stage compressor has clearance spaces equal to 2% of its

volume. At 100-lb. receiver pressure, therefore, which calls for eight expansions in the clearance, there is a direct loss of volume by clearance of 16% in the average single-stage machine.

Piston and Piston-Rod Leakage.—No piston is ever tight in an air-compressor, even when it is new and fitted with the best of rings; neither can this be expected, for it requires gaskets and many bolts to keep a cylinder-head tight, and heavy pressure from a long wrench to make a pipe-thread tight. It is evident, therefore, that the contact the rings make with the cylinder walls is not sufficient for a joint. This can easily be tried by taking an inlet-valve out of one end of an air-compressor and an outlet-valve from the other end; admit the receiver pressure at 100 lb. into the cylinder, and the air will rush out through the inlet-valve opening in proportion to the condition of the cylinder piston and rings. Inasmuch as sometimes this becomes a great loss in an air-compressor, an operator should, upon installing a compressor, make the above test to familiarize himself with the normal leakage when the compressor is new. Then, when the machine is not delivering its proper quantity, a second test will show the difference. For this purpose I use a plug to screw into the inlet-valve opening. This plug has a round hole bored in it of such a size for any given compressor that the pressure indicated on a gauge also attached to the plug shows somewhere from 2 to 10 lb. By a reference to a 'Discharge from Orifices' table, the approximate volume flowing out may be determined and recorded. If after use this machine requires overhauling, a repetition of this test will show the additional comparative loss, and thus the condition of piston and rings may be determined without removing them. Speaking of rings, it is seldom that snap rings, even with eccentric circumferences, are good enough for compressors having cylinders over 8 inches diameter. Sectional rings provided with springs are better.

The leakage around the piston-rod through the packing gland may be considerable when a compressor is carelessly operated, or it may be practically nothing with good packing, a smooth rod, and proper attention. Taking average cases, it may be assumed that there is a general loss of 3% of the volume of the cylinder due to leakage around the piston and piston-rod. In testing for such leakage the piston is placed in different positions and air under pressure that corresponds to the position of the piston is admitted, and the results are then properly averaged.

Valve Leakage and Slippage.—Poppet valves are seldom perfectly tight, and at ordinary operating speeds do not close exactly at the end of the piston stroke. All resulting leakages are against the volumetric efficiency of the compressor. In the inlet valve comes, first, the slight slippage due to delayed closing when some of the air in the cylinder will be pushed out again; and when the valve is seated, if it is not absolutely tight, a certain quantity is being pushed out as compression progresses. In the outlet-valve the slippage and leak help fill the cylinder as the intake stroke progresses, thus reducing the intake volume. I determine these leakages in the same manner as with the piston leakage, by means of a pressure gauge and small nozzles, using the orifice discharge tables to get the quantity. In ordinary machines these valve leaks and slippages will amount to 4% of the cylinder volume. It will readily be seen that the slippage is a function of the piston speed; the greater the speed the greater the slippage, until a speed of 200 r.p.m. is attained, which is practically the limit for ordinary poppet valves. Indeed it may be less, depending on the weight of the valves. I remember trying a 10 by 10 compressor driven by a water-wheel so that any desired rate of revolution could be maintained. A hole was drilled in the side of a receiver and gauge reading taken at various speeds. At 168 r.p.m. the maximum reading was taken, and this reading was maintained up to 180 r.p.m., when the pressure fell for any increased number of revolutions. If mechanical valves had been used the revolutions could have been materially increased; just what the limit would be, I do not know.

Temperature Considerations.—These are of great impor-

tance and are extremely difficult to determine. It is evident, however, that the lower the intake temperature is, the greater the weight and consequently volume of air the compressor will deliver. It is desirable, therefore, to draw the air from the coolest place adjacent to the machine, and at the same time from a place free from fume or dust. It is also evident that the hotter the inlet-valves, the more heated the intake air becomes in passing through and over their hot surface, and the greater it will expand, thus reducing the weight taken into the cylinder and consequently the resultant volume of compressed air. The same is true of heated cylinder walls and heads. Inasmuch as water-jacketing is the only method in a single-stage compressor for reducing these temperatures, it is important to see that the water-jackets are free from sediment and that a quantity of water is passed through the jackets sufficient to show no noticeable difference of temperature in passing through. The idea is to keep a cylinder cool in order to get as great a weight of air as possible into it.

An experiment can readily be made to show this temperature influence. Drill a hole in the air-receiver and note the gauge pressure when it becomes stationary with the compressor running, then close off the jacket water and note the pressure gradually drop, showing the loss of volume. In average single-stage machines, 7% is not too much to allow for losses due to temperature influences.

Summing the losses, they are: (1) Clearance losses, 16%; (2) piston and rod losses, 3%; (3) valve leakage and slippage, 4%; (4) temperature losses, 7%; making a total of 30%. In other words, the compressor gives 70% of its catalogue free-air rating, when operating at catalogue speed and 100-lb. receiver pressure. This seems quite a loss, but it is practically true, and may be considered inherent in the ordinary poppet-valve single-stage compressor. Now, if this condition exists to start with, and never grows better, but always worse by wear, it is evident that the best care and attention must be given the machine. I have noted many machines of this type that were not giving 50% volumetric efficiency from being in bad repair and unskillfully handled. It becomes evident, therefore, that if an air-compressor is not doing its work, very material gains can be made by investigating the sources of loss as herein indicated, and making necessary repairs. It is also self-evident that these losses will decrease in some ratio as the pressure decreases, and by experiment the result is about as follows:

Volumetric efficiency at 100-lb. pressure, 70%; at 80 lb., 77%; at 60 lb., 82%; at 40 lb., 85%; at 25 lb., 88%. In other words, the same compressor will give 25% more air at 25 lb. than at 100-lb. receiver pressure. Now, inasmuch as 25 lb. is the working pressure of the low-pressure or intake cylinder in a two-stage machine, it needs no comment to show why it is desirable. It is also evident that a purchaser is getting 25% more for his money, independently of other gains, when buying a two-stage compressor.

While compressors are rated by displacement which does not show their true output, most pneumatic tools are very much underrated by their builders, especially pneumatic riveters, chippers, and boring machine; some as much as 50%. An air-compressor need not be condemned for lack of duty, therefore, if it does not operate as many tools as rated in the catalogue.

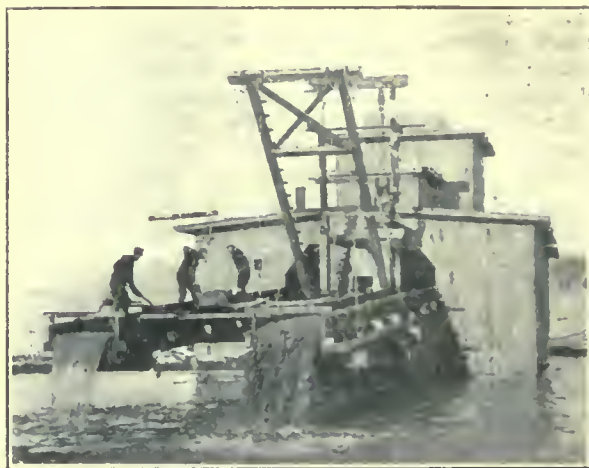

For first aid for a crippled compressor, it may be suggested that excessive piston clearance may be remedied by putting a thin piece of boiler plate on the piston, or thin paper gaskets under the heads, if possible. Piston and rod losses point to re-boring the cylinder, to new rings, and to need of proper packing. Valve leakage demands re-grinding; valve slippage, the putting in of heavier springs and re-grinding, and, if revolutions of the compressor are excessive, these must be reduced. Temperature losses may be decreased by giving cooler inlet air, cooler jacket water or more of it, or by cleaning out the jackets. If a compressor lacks but a small percentage of furnishing air enough for its work, and the preceding suggestions have all been taken advantage of, then a 'booster' consisting of a rotary blower may be attached to the suc-

tion of the compressor so as to give an intake pressure of one or two pounds, and this will materially increase the output of the compressor. Care must be taken to supply a blower having at least 15% greater capacity than the compressor.

Tin-Dredging in Alaska

By T. M. GIBSON

A dredge was installed this year on Buck creek in the York district of Seward Peninsula for the purpose of mining stream-tin. It is, I believe, the only dredge ever built to mine tin in territory belonging to the United States. The material for this dredge was landed on the ground August 7, and it was completed and ready to run September 6, though, on account of the dam behind the dredge washing out, and some engine troubles, operations were delayed until September 10. This dredge was designed by W. W. Johnson and H. G. Peake and was financed by them and some of their friends in San Francisco. It has a 2 $\frac{3}{4}$ -ft. bucket-line and its power is supplied by two 40-hp. Union gas-engines. It uses 160 gal. of distillate per day. The material passes from the buckets into a 4-ft. revolving screen 13.5 ft. long and having 3-in. perforations.

TIN-DREDGE, SHOWING ONE SLUICE BEING CLEANED UP.

The oversize passes to a conveyor-belt running almost horizontally and is dumped just far enough astern to give clearance. The undersize drops into a steel box open at the lower end and set at such an angle that the material flows freely into either of two 42-in. sluices which run to the stern and project 44 ft. beyond, being supported by cables from the rear gantry. A cut-out partition in the steel box enables the operator to send the material down one sluice-line while the other is being cleaned up. The water is supplied by a 10-in. centrifugal pump. A 6-in. pipe leads to the head of the sluices and an 8-in. pipe leads to four 3-in. nozzles in the screen, which spray upgrade against the downward moving material. The sluices contain Hungarian riffles 2 $\frac{1}{2}$ in. deep, set 2 $\frac{1}{2}$ in. apart.

The dredge was closed down October 15, so that the crew could catch the last boat down from York this fall. Between September 10 and October 15, 92 tons of tin concentrate, having an average content of 64% tin, was mined. Of this, 74 tons was shipped to Seattle on the *Corwin*. The rest was shipped out on the *Durbury*, a small gasoline schooner leaving later. The concentrate at present quotations is worth over \$500 per ton. Heretofore, small lots have been shipped from the York district and had to go to Cornwall, to Wales, or to Hamburg, Germany, for treatment, but it is now thought that arrangements may be made to treat it on the Pacific Coast. Mr. Johnson thinks the output will exceed 300 tons of concentrate next season. The phenomenal success of this little dredge seems to open a very alluring field for others, but it must be kept in mind that so far as known, the rich tin-bearing grounds are confined to Buck creek and this company has it all tied up.

The London Market for Mining Shares and Metals

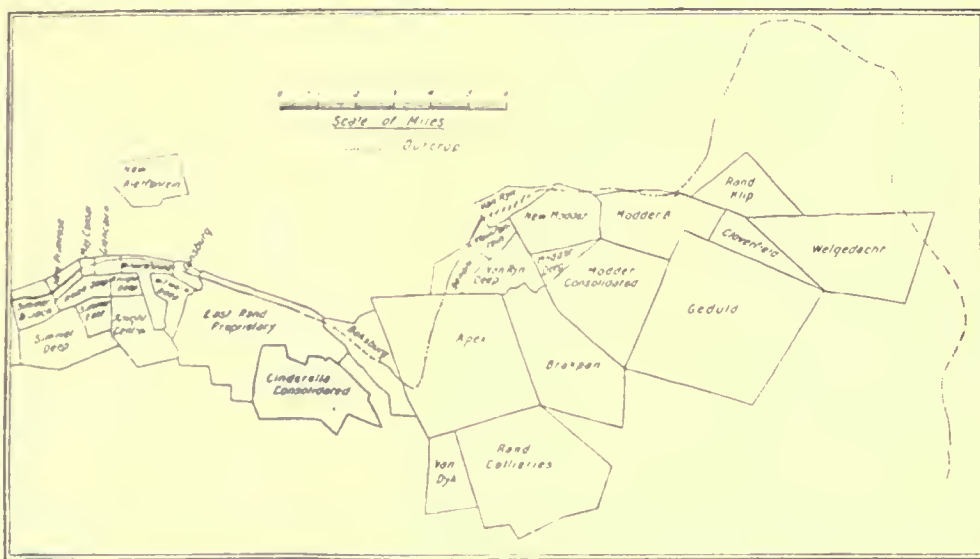

By T. A. RICKARD

The past year has been marked by profound political disquiet, which has been so widely distributed as to affect both mining operations and those financial arrangements on which the miner depends for capital. Revolutions in Mexico and China, military aggression in Morocco, Tripoli, and Persia, serious friction among at least three of the Great Powers, has all shaken that pocket nerve which is the most responsive in the human anatomy. The Mexican revolution appears to have run its course to a pacific consummation, and the hope may be entertained that the political stability of the Government in that great mining region will tend to encourage further exploitation. China is still in the throes of an upheaval that seems likely to cause a complete abandonment of hoary anachronisms; but it is improbable that industrial peace will be restored for a long time to come. The mining interest in this revo-

undergone several shocks, besides a gradual realization of the fact that the Rand has passed its zenith. An enormous quantity of gold remains to be dug out of the ground and many millions of pounds sterling are yet to be distributed among shareholders, but the glory is departed. The best features of mining at Johannesburg have now been discounted, and in future the unexpected will be unpleasant. Much new and original work remains to be done in the technical departments, but the great era of expansion as regards mining operations shows signs of termination. At the beginning of the year the firm of Wernher, Beit & Co. distributed its assets among two holding companies, the Rand Mines and the Central Mining & Investment Corporation. Alfred Beit died four years ago. Sir Julius Wernher is an invalid and has been compelled to withdraw from active business. Thus a big

[illegible]

Socially the year 1911 was rendered noteworthy by the coronation of King George V, with attendant celebrations and festivities, all of which interfered with the routine of business and the progress of speculation. After the coronation came an exceptionally sunny summer, causing the holidays to be unusually prolonged. To our American friends it may seem that such incidents should not affect business, but they do. It has been said that my fellow-countrymen take their pleasures sadly; they certainly take their holidays religiously. For several months the City was half deserted by its most dynamic personalities. Speculation languished. Then came wars and rumors of wars, a railway strike, a couple of mining fiascos, followed by the usual November fogs and cold rain, enough to dampen the spirit of Sunny Jim himself. On the whole, we are well rid of 1911, and have good reason to expect better things in 1912. A comparison of quotations, given on another page, will exhibit the trend of the market since this review was written a year ago. The general tendency is downward.

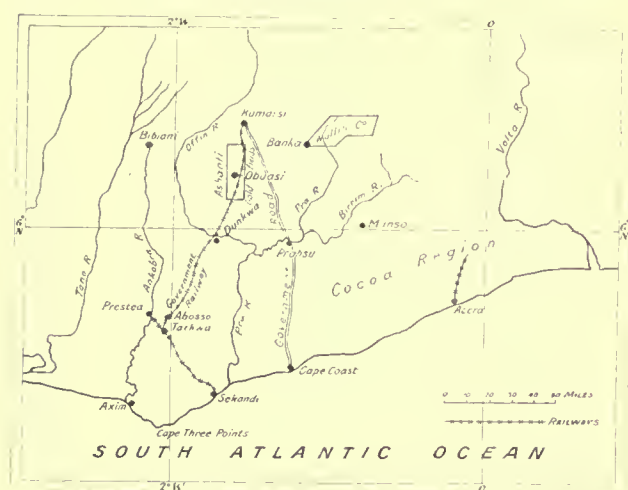

THE EASTERN RAND.

factor in Rand affairs is no longer potent. The financial house next in rank is the Consolidated Gold Fields of South Africa; this also is extending its activities outside of the place of its origin, and has acquired interests in California, Canada, Trinidad, and Mexico. Other South African houses have followed suit. It may be accepted that the well informed recognize a necessity for diverting energies hitherto concentrated on the Main Reef series in the Transvaal.

Turning to the 10 representative quotations, it will be noted that the East Rand Proprietary, after a tardy and discreditable confession of a vain effort to carry out a too ambitious programme, has suffered a drop of 10% in its market valuation. The life of the Robinson is drawing to a close, hence a decline in the appraisal that should have come earlier and more gradually. The Meyer & Charlton affords a pleasant example of stability and good management. The big consolidations of the Crown Mines, Rand Mines, and the Randfontein groups have suffered from the East Rand exposure and from the shortage of native labor. This last has been a constant hindrance to the fulfilment of large-scale plans of operation, and it is only recently that frank acknowledgment has been made of it. The companies that have completed new and large milling plants during the year have tended to check the drooping tone of the market and will be prominent in 1912. I refer especially to the two Modderfontein companies, the City Deep, and the Brakpan. The City Deep has suffered from errors in mill construction and from rumors concerning the title to its mining claims.

due in part to an uneffectual effort on the part of market operators to stimulate a boom, that is, to drive the public into a state of irrational optimism. The boom spluttered like a damp fire-cracker, and is succeeded by a gloom all the denser for the brief pyrotechnics. The production of gold shows an increase, but it is so slight as to be disappointing. An analysis of the Rhodesian returns indicates that 24 out of the 162 productive mines yield 70% of the gold output. Further, the four biggest producers (the Globe & Phoenix, Giant, Eldorado, and Lonely Reef) contribute 36% of the total output. The Rhodesian market is the most cleverly manipulated of any mining department and the ledger-deman of share-dealings is nowhere carried to so dangerous a point. Reports given to shareholders are usually both belated and cryptic. However, as against the slight gain in production and the manifold signs of irresponsible finance, it is pleasant to record the development of several fine properties, quite capable of becoming the basis for profitable mining, if that operation were not tied to over-capitalization and excessive appraisals that leave no chance for sound business. Among the new mines are the Shamva, an agglomerate deposit that continues to open-up splendidly, the Cam & Motor, with several lenticular ore-shoots of excellent grade, and the Lonely

WEST AFRICAN GOLDFIELDS.

Reef, a small but rich and continuous orebody. The last mentioned affords an excellent example of ill-regulated optimism; the vein is rich but narrow, the mill has a capacity of 4000 tons per month, at which rate two levels must be opened up annually, arguing unbounded confidence in the persistence of the ore-shoot. The shares stand at £3¾, or over \$4,500,000 for a mine having only about \$1,500,000 of profit assured. The Globe & Phoenix is the most productive mine and holds its own, despite some minor set-backs. The Giant has lost its orebody by a fault, and now faces an uncertain future. The British South Africa or 'Chartered' company, which is the landlord of Rhodesia, has not declared a dividend as yet, but holds out the promise of doing something for its shareholders soon. The Tanganyika Concessions, the big Anglo-Belgian copper company, with mines in the Congo Free State, has been the sport of bulls and bears, chiefly the latter, throughout the year. This enterprise represents the application of much energy, more money, and less technical experience than is advisable at this stage of the world's history. The coming year should see a show-down, for a smelting campaign was started in June and the publication of results cannot long be deferred.

WEST AFRICA has had its set-back in the shape of a fiasco at the Prestea, the company representing the consolidation of the Prestea Block A and the Prestea Mines. When the 110-stamp mill was approaching completion it was stated by the new manager that only enough ore for half its capacity could be supplied. On the other hand, the Ashanti Goldfields is doing well and has opened another ore-shoot of a most promising character. Other mines of which good things were expected have languished. The Gold Coast is affected with a malaise that deadens the energy of every

white man and hinders the completion of plans cheerfully devised in London. Lack of labor, or lack of laws regulating the native laborer, has become a familiar complaint. The companies are co-operating and are doing their best to get an unsympathetic colonial Government to aid them in this first step to industrial development. The Government is not quick to respond; it appears to look upon the mine operators as the 'bold bad men' of a nursery ballad and mulets them of even scant profits by imposing excessive rates for transport of supplies and machinery on the Government railways. The output of gold is increasing, but nothing like as rapidly as was expected. Profits are small because the initial outlay is heavy, time is squandered, and management is rendered costly by climatic obstacles.

As a supplement to gold digging, the West African region boasts the beginning of a petroleum industry and of alluvial tin mining. The latter has brought Nigeria much

THE GOLDFIELDS OF WESTERN AUSTRALIA.

to the front during 1911. At the end of the year the public interest in a dozen tin companies shows signs of increase. Eleven years ago the first samples of tin ore were sent by the then High Commissioner to England. Now a hundred companies and syndicates are at work on the Bauchi plateau and elsewhere in Northern Nigeria. A branch railway is being built to the placer mines. Water conservation during the wet season has helped to prolong productive operations. The landlord of this region is the Nigeria Company. At present shipments are being made ranging from 5 to 40 tons of concentrate per company per month, the total being about 150 tons of stuff containing 50 to 70% tin. Owing to the prevailing high price of the metal a further increase of activity is probable.

AUSTRALASIA, as a mining region, is largely divisible for market purposes among Western Australian, Broken Hill, and Copper departments. Of these, Broken Hill has been most prominent during 1911, owing mainly to the discovery of a new run of ore in the British Broken Hill Proprietary, a mine whose career has been chequered by over-capitalization and other misfortunes. The mine was shut-down in 1907 and the company sold its tailing heaps to the Zinc Corporation, receiving over \$500,000 in cash. With this

money fresh exploratory work was undertaken. In 1910, a new orebody was cut on the 800-ft. level, and in 1911 this was proved to be a discovery of the greatest importance. Evidence indicates that this ore is not part of a new lode, but belongs to the main ore-channel traversing the series of mines that have made Broken Hill famous for its silver, lead, and zinc production. A high price for the base metals has helped Broken Hill and the successful beneficiation of old dumps, as well as of low-grade refractory ore in the mines, has lifted share quotations. The process companies are still waging a bitter fight, one of the events of the year being the unfavorable decision obtained by the Elmore companies in their suit against the Sulphide Corporation. This particular quarrel, however, represents only a small part of the cross-fire of litigation.

In Western Australia the gradual exhaustion of the Kalgoorlie bonanzas is repeatedly emphasized by acknowledged reduction of ore reserves and decreasing dividends. New mills and new managers are introduced to stem the ebbing tide, but in vain. Among the big mines the Golden Horse-Shoe has suffered from a drastic diagnosis of its condition and the Kalgurli has had to submit to an unpleasant stock-taking. Among the outside mines the Sons of Gwalia holds its own, a new orebody having been traced from surface to the 14th level. The Great Fingall has aroused fresh hopes by the discovery of an orebody in the bottom of the mine, giving some color to a favorable geological surmise. Efforts to regain public interest in new districts have proved futile by reason of the failure to find any new goldfield justifying keen interest. The Bullfinch boom, started in a most reckless manner at the close of 1910 and endorsed by the Premier of the State, came to an inglorious end early in 1911. The shares of the original mine have fallen to 10 shillings from a height of £3½, while the 'pups' or extensions have gone to the liquidation morgue.

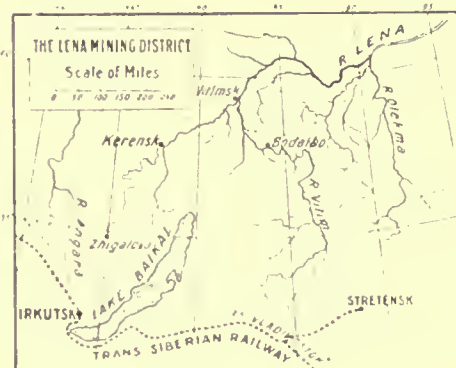

The crisis at the Waihi mine in New Zealand is one of the notable events of the year. From a quotation of £10½ in 1910, the price of the 500,000 shares dropped to 2¼ in 1911. This was due to a belated acknowledgment of the fact that the several lodes in the mine had become poor, necessitating a radical diminution of the gold and silver output. The impoverishment became marked just below the lower limit of oxidation, and is also due in part to a change of country-rock. This was for many years the finest gold mine in the world; hence the fiasco is much regretted.

THE AMERICAN department includes the Mexican group. It is first in alphabetical order, and the first in honor is the Alaska Treadwell. The mine, with its affiliated neighbors, the United and the Mexican, on Douglas island, constitutes one of the very best exponents of the application of technical science and good sense to mining. The management deserves the greatest credit for economy and skill, both of which, fortunately, have been favored by a persistent orebody of big dimensions. The Camp Bird is now a Mexican enterprise, the old mine in Colorado being nearly exhausted, after yielding a magnificent return, part of which has been re-invested in the purchase of the Santa Gertrudis at Pachuca. There the new mill has recently started, the mine is opening up well in depth, and a profit of \$1,000,000 this year and \$1,500,000 next year is anticipated. At El Oro the year has been marked by the transfer of the management of the Mexico mine from the Exploration Company to S. Pearson & Son. The transfer was not effected without heart-burnings, but it was followed by the reappointment of the former resident manager, and has not been associated with any marked drop in quotations, which remain on the rose-tinted level of French optimism. The Esperanza has had some setbacks, and the El Oro is doing nobly despite its waning vigor. Oroville Dredging has gained interest by the completed purchase of the Pato concession, in Colombia, which it is hoped will restore its shattered fortune. West Mexican is not quoted, being in difficulties with its famous Rosario mine near Guadalupe y Calvo, in Chihuahua. The Tomboy has again prolonged its life by acquiring adjacent property, the approaching exhaustion of the Argentine being compensated by the purchase of the southern part of the Rev-

enue Tunnel property. This company's record exhibits a rare example of management in the interest of shareholders. Other notable events in the American department were the issue of bonds by the Natomas company, controlling dredging and agricultural property in California, and the Granville, a mining company organized by A. N. C. Treadgold, H. C. Hoover, and A. C. Beatty, to exploit a part of the White Channel in the Klondyke district. No public issue was made, all the capital required being readily subscribed.

The quotations for one or two Ontario shares suggest the brief excitement created by the gold discoveries at Porcupine. Bewick, Moreing & Co. brought out the Northern Ontario Exploration Co. and enlisted the co-operation of other financial houses. A block of Hollinger shares was acquired, but was sold on the first big rise. Lack of real information, in the form of assay-plans of the rich mines, has nearly killed public interest in the Ontario goldfields.

ASIA. No new discovery of note has been made at the Kolar gold mines in Mysore, India, during the year, but the developments have been satisfactory, especially at the Mysore and Nundydroog mines. The Champion Reef has been in poor ground for four years, but the ore disclosed during the year is better than a year ago, and the profits are consequently greater. The most important factor in the improved situation on the Kolar field has been the reduction in costs consequent on cheaper electric power. Of other gold-mining districts in India, the Dharwar has

proved a failure and work has been suspended; on the other hand, the Anantapur goldfield is developing in a promising way.

In Siberia the Lena Goldfields is remarkable as the most productive alluvial gold mine in operation anywhere. The ground is permanently frozen, as in the Yukon, and the gold lies on bedrock 100 ft. below the surface. Drift-mining accompanied by steam-thawing is employed. In the season of 1911 the output of gold was £1,619,406, or \$8,047,030, from 881,000 cu. yd., or an average of 10 dwt. per yard. The cost averaged \$6.21 per yard. This seems appalling, but it is due largely to difficulties of administration and the expensive character of the methods required to extract the gravel. In the far east of Siberia, the Orsk Goldfields has erected a dredge, from which much is expected. A preliminary run with a stacker-scow has shown a yield of \$1 per yard, but it is not likely that this is a correct average of the ground.

COPPER. This group is important and interesting. Some of the Australian mines have been unfortunate. At the Great Fitzroy, in Queensland, the oil-flotation process proved a failure in the concentrating mill until the end of the year, and smelting of selected ore gave scanty returns. At Great Cobar, in New South Wales, the acquisition of a neighboring gold-quartz mine has been good policy, as affording a profitable form of silica for mixture with the pyrite ore, but the underground operations in the parent mine had been neglected during the reorganization of the smelting portion of the undertaking. The Poderosa, in Chile, has made many shipments of 22% ore, but the lode is pinching in depth and operations have been hindered by heavy snows followed by flooded workings. The Siberian group has been conspicuously successful. During the

year the Atbasar passed under the control of the group that is operating the Spassky, by the transfer of a block of shares held by an American group, which still holds a large interest in the Kyshtim. These three companies, unlike in many respects, are linked in several ways, and represent the fit survival of a former boom. The Sissert estate, another Russian copper property, in the Ural region, has been the objective of examinations and negotiations on the part of British operators, who, failing to meet the terms of the vendors, have seen the estate pass into the hands of a Russian group, which is likely to develop the mine and then give the Britisher a chance to come in on an upper story.

The Arizona Copper at the end of the current year has completed plans for re-arranging its plant. Several Norwegian copper mines are controlled in London, but labor troubles and other causes less transitory have depressed them. The Caucasus Copper company, which is controlled by J. P. Morgan capital, is still in difficulties. Large sums of money have been spent and the best English and American advice obtained. The concentration plant, as reorganized by James Colquhoun, late of Arizona, and the smelter, under the management of W. R. Van Liew, at one time at Anaconda, are both in excellent condition, and the reserves of low-grade ore are enormous. The climatic conditions are much against success, and the heavy capitalization and debts left by previous mismanagement will always militate against the reputation of this company. The Messina mine in the northern Transvaal, though containing rich ore, has not made any profit so far, because of the inability to smelt on the spot and the lack of communication. The prospects are now more hopeful, because the railroad will be shortly completed, connecting the Rhodesian railway system with Delagoa Bay, and with Pretoria, Johannesburg, and Cape Town. The most important event, however, has been the discovery of a coal seam about thirty miles away; this has been promptly bought by the company. A year or two ago the Ferrobamba copper property, fifty miles south of Cuzco, Peru, attracted much attention in London. Owing, however, to the lack of support obtained here by the promoters, the control has been allowed to pass into the hands of A. C. Burrage, of Boston, and he is now maturing plans for the erection of a concentration plant. The Anaconda and Rio Tinto reflect the improved market for copper; the big mine in Spain is believed to be about to increase its production of pyrite. Copper producers everywhere end the year in a hopeful mood.

TIN. The market for tin has been disorganized by a corner on the London Metal Exchange, where metal produced in the Malay States and Australia has hitherto been the only sort recognized officially in connection with speculations. The other brands produced in Cornwall, Bolivia, and Germany have now been included among the 'good delivery,' so that the erratic course of prices ought to be checked. The high price ruling for tin during the year, culminating in a quotation of £230 per ton in May, has naturally stimulated search for the metal. A group of mines in the Federated Malay States, notably the Tronoh, Gopeng, and Tekka, owned largely by enterprising Cornishmen, has done remarkably well. This has led to one or two flotations of extension claims. I have already referred to the new supplies coming from Nigeria, but I might add here that some of the concentrate unfortunately contains many minerals besides cassiterite. A more important source of tin in the future is South Africa. Already some of the mines in the northern part of the Transvaal are yielding handsomely, the Rooiberg and the Zaaipplaats being specially notable. Deposits have been discovered in various parts of the Rhodesia and German Southwest Africa that appear to be of considerable promise, while the Swaziland gravels continue to be productive. In Bolivia, the lodes containing complex tin ores are being exploited actively, and much modern machinery is being erected. As regards Cornwall, it is worthy of record that the new vertical shaft at Dolcoath is now ready for work and the cost of mining will be reduced considerably in the near future. The dressing cost also ought to be reduced on account of the provision

of improved crushing plant. The South Crofty is undoubtedly the best example of modern mining and concentration in Cornwall at the present time. The cost and the yield are two-thirds those of Dolcoath, and the ore is complex, containing much wolframite and arsenopyrite. A notable event has been the appointment of an outsider, E. S. King, formerly of West Australia, to the management of the Carn Brea & Tincroft, with the consequent introduction of more modern ideas of mining and dressing. The results achieved by the Cornwall Tailings Co., on the treatment of the old Carn Brea dumps, provide a practical demonstration of the imperfection of the old ideas regarding the concentration of tin ore. The scheme for dredging the alluvium at Goss Moor has been put into effect and the first results are promising. With these few exceptions, the outlook for Cornish mining is as unfavorable as it has been for the last thirty years.

ZINC. Zinc has occupied a large share of attention in London during the past year. The zinc problem at Broken Hill continues to be studied closely from various points of view. The Broken Hill Proprietary is now in a position to produce metallic zinc and is considering the advisability of starting an iron-smelting industry for the purpose of manufacturing galvanized sheet and wire, the most profitable outlet for the zinc. The other producers of zinc concentrate are centering their attention on the beneficiation of the accumulated slime, which is high in both lead and zinc and not amenable to table concentration. The plan of the Sulphide Corporation was to add slime concentrate by flotation to the zinc product, so as to conform with the modern requirements of the British and European smelters for a zinc material high enough in lead to save silver in the retort residue. But when the mixture was offered, all sorts of difficulties arose. In consequence, the Broken Hill mines have during the past year been investigating the possibilities of the electric furnace for the production of lead, silver, and zinc direct from the slime. The first system tried was that at Trollhättan, Sweden, but as this did not give good results, attention has been turned to the Imbert-Fitzgerald type of furnace. The cost of electric heat and the incomplete production of molten metallic zinc have so far been against the success of these processes, but there can hardly be any doubt that this method of treatment will provide the eventual solution of the complex sulphide problem.

OIL. The interest in oil has suffered from a reaction following the boom in the spring of 1910. During 1911 one or two Californian enterprises were launched on the London market, but they sailed into troubled waters. Maikop has proved disappointing. The original gushers came from relatively small bodies of petroliferous sand in the shale, and later exploration by boring has failed as yet to confirm the geological supposition that a series of oil-sand formations existed in that part of the Caucasus region. Trinidad has been the motive for several new issues, but the Trinidad Oilfields remains the premier company. The Peruvian companies, notably the Lobitos and London Pacific, are giving excellent results. But speculation in oil is not lively; in the shares as in the wells, too much water is mixed with the petroleum.

The past year has been one of depression, varied by moments of inspissated gloom, but no great destruction of credit has occurred; hence the bad times of the immediate past need bear no sequel of further trouble. British trade returns indicate a continuous expansion of industry. The cheerful spots are occupied by the Broken Hill, Siberian, and tin mining departments. The comparative scarcity of tin is stimulating the search for that metal, and the growing demand for zinc is prompting metallurgical research in the treatment of complex base ores. West Africa and Rhodesia have gained ground slightly. The Rand has retrograded in market estimation. Excessive holidays and disturbed politics have hindered sustained speculation. The market is therefore burdened with undigested securities, but its dyspeptic feelings could be relieved by even a small dose of reasoned optimism. Eras of depression and elevation come in cycles; the London market ought to be lively in 1912.

Pebble Efficiency in Tube-Milling

By A. W. ALLEN

The question of the efficiency of pebbles of various sizes in tube-milling is an open one. In the earliest application of these machines for sliming gold ores at Kalgoorlie it was a common practice periodically to overhaul the contents of the mills and to reject the smaller flints. Some advantage evidently accrued, although the question was not discussed, and there was a want of unanimity of opinion as to the advantages gained by the operation.

The bulk of the sliming action in tube-mills results from the direct impingement of the pebbles, one upon the other. This is also the easier action to consider theoretically. If it be supposed that the contained pebbles in a tube-mill are perfect spheres of 1, 2, 3, and 4 in. diam, their respective masses are in the ratios of 1, 8, 27, and 64; and since the velocity at point of impact would practically be the same in each case, the available energy can be roughly estimated as follows:

(1) At point of impact,

Diam. of pebbles.	Momentum ratio.	Energy ratio.
1 inch	1r.	1
2 "	8r.	8
3 "	27r.	27
4 "	64r.	64

(2) Assuming one point of impingement per pebble, in each cubic foot,

Diam. of pebbles.	Points of impingement.
1 inch	1728
2 "	216
3 "	64
4 "	27

(3) Energy ratio times frequency equals composite efforts per unit volume,

Diam. of pebbles.	Energy ratio.	Frequency.	Unit of effort.
1 inch	1	1728	1728
2 "	8	216	1728
3 "	27	64	1728
4 "	64	27	1728

In place of a statement of simple fact the above details may seem labored, but the idea is to emphasize the utility of the smaller, as well as the larger, pebbles. A composite equality of available energy per unit volume does not, however, necessarily imply identical performance with pebbles of any size, under all conditions. Fracture, and resultant effect, will depend on the friability of the ore as compared with the size of the particles to be broken and the momentum of the mass that is expected to break them. Present-day tube-mill practice indicates that a cylindrical mill operates with a mixture of pebbles of all sizes below 4 or 5 in. diam., with the exception of a proportion of the smallest, which are periodically discharged with the pulp. Attention is seldom paid to the question of feed, but it is evident that efficiency is sacrificed if the material fed contains a proportion that is too coarse even to be fractured by the smaller pebbles; that is, energy is being lost if any individual impact is unproductive of result.

Under these conditions a reduced feed often indicates an improved efficiency, the probable reason being that, with the full feed, coarse sand is found even at the discharge end of the mill, and, in consequence, the smaller flints have no opportunity for doing useful work on particles of ore proportionate to their size. By lowering the feed the coarse sand may be uniformly reduced in the first half of the mill. The smaller pebbles in the second half then have an opportunity of doing useful work in return for power expenditure. From which may be inferred that an efficiency with regard to feed-volume is strictly relative to the grade of ore being introduced.

In considering the action of the larger pebble on a finer grade of material the area of impingement is proportionately increased after fracture of the largest sized particles occurs; and any unspent energy remaining is concerned with the pulverizing of a larger area of smaller particles. The energy expended by the larger pebbles can never be unproductive as long as the unclassified product from the mill contains a proportion of unslimed ore.

Tube-mills are used for sliming a product previously milled, and also for re-grinding a coarse battery product preparatory to classification and leaching treatment of the remaining sand. Where pebbles, and not rough cubes of the ore itself, are used for grinding purposes, it would seem that the tube-mill is better adapted for sliming than for re-grinding; and that where the output from the batteries is through a coarse mesh, another class of pulverizer or grinder should intervene between them and the tube-mills in order to handle and reduce the proportion of coarse sand produced.

The Future of Concentration

By M. P. BOSS

Following the introduction of the Frue vanner the public held complacently the thought that that machine would do about all that could be done in concentration. The years that have elapsed since have unveiled additional complexities in proportion as understanding has increased. Sizing and classification have long been in a measure appreciated, but even today are broadening into wider and more universal practice, and are evidently destined to much greater consideration by the general public. It has been and is customary to measure success by profits of treatment, quality of work often being sacrificed for quantity; and often the loss is a final and permanent one. This matter may yet run counter to the conservation tendency, and thus stimulate a desire to get all that mechanical genius can get—to get out by automatic mechanical means what can now be gotten out by a batea through skillful hand manipulation. At the present stage of the art little progress can be expected by haphazard means. A thorough understanding of the principles involved in the obstacles that yet so thwart engineers is essential to cope with today's problems. This is particularly true in slime treatment. New devices bring hopes, to be followed by disappointments, yet the why and how is continually becoming better understood.

In all concentration two active agents are involved, impellant energy and retardation. Retardation may be liquid and non-directing, or it may be rigid and guiding. In a feed composed of true spheres of absolutely equal size, a concentrate could undoubtedly be completely segregated from a gangue of but little less specific gravity, even if the material was so fine as to be classed as slime, by machines now on the market. In true spheres 'impellent energy' (as of gravity) is in ratio as the *cubes of their diameters* multiplied by their specific gravity, while 'liquid retardation' (as in precipitation) is in ratio as the *squares of their diameters*. This unfailing law is the bogey that is the cause of the greatest troubles in intelligently manipulated concentration. Two spheres of equal size but of unequal specific gravity would meet, in liquid precipitation, equal resistance, their displacement being the same, while the 'impellent energy' would be greater in the heavier sphere. Thus a large grain of gangue will sink faster than a small grain of concentrate. This is a clear reason why thorough sizing is desirable. The closer the sizing, the easier and better the dressing. It is easy to size a coarse material, but the difficulty multiplies with fineness, and in slimes one particle may be several times the diameter of another, an associated particle. From this rises the difficulty with slimes, a difficulty which probably never can be wholly overcome, so that there is little hope of slime treatment through 'liquid retardation' (precipitation or longitudinal hurling).

Rigid and guiding retardation, as on a table, or in a batea, introduces other principles, the horizontal plane

estopping precipitation and the finer particles finding their way through the interstices between the larger grains and resting upon the bottom, where they are in a measure protected and are less affected by currents that sweep along the coarser grains. The efficiency of this action decreases with depth of material and is a factor of grain diameter. The bed should be thinnest with slime, as a thick bed brings into play the 'liquid retardation' law, that precipitates the larger grains of gangue faster than the fine grains of concentrate. These are principles to consider in regard to riffles and to table-deck treatment, to avoid as much as possible ill effects from liquid retardation. When a concentrate particle has once reached bottom all effort should be made to keep it there. To this end riffles should be so designed as not to have a turbulent raising effect below them, unless material is very closely sized or of widely differing specific gravity.

The foregoing implies that all unenriched concentrate material might be segregated from a gangue, even if only slightly heavier, when properly classified. The term classified, rather than sized, is used here advisedly. Material can be thoroughly sized by screens only. Classified is a broader term and includes hydraulic classification, which is a process based on the law of liquid retardation, wherein the heavier particles are smaller than those that are of lighter specific gravity. As we have seen, the latter is more suited to lateral table-deck treatment and the former to liquid retardation. In looking at the acres of concentrating machines in one of the great modern plants of today and realizing that the same machines are greatly overworked for commercial reasons, one quite naturally drops into computing the percentages of the total area that is actually segregating concentrate from gangue, and it is small.

From the present viewpoint, where is the relief? As has been noted, no space is wasted. Yet it is quite probable that in some future day more work will be done on a less area. About as the flying machine was to human travel a half dozen years ago, so centrifugal concentration is viewed today. Yet an impellant energy many times augmenting that of gravity may be developed by high centrifugal action, some like characteristics existing in both, yet with complications abounding for future solutions. When the capacity of present machines has been greatly increased without increase of cost, then a better quality of work may be expected. While very great progress will likely be made in the near years to come, there will likely be ample field for study for many years.

THE wealth of Sweden lies chiefly in its forests and mines, especially the iron mines. The forests are not only vast, but the wood (chiefly pine) is of a high quality, owing to slow growth. This makes it particularly fit for wood pulp, especially that intended for manufacture of so-called 'kraft' paper, which is tougher and stronger than paper made of lower-grade, softer wood. The result has been that Swedish wood pulp and Swedish kraft paper have been more and more sought after, and the export of these articles shows a steady increase. The extensive iron mines of Sweden, especially those of Lapland (northern Sweden), contain probably the largest high-percentage iron-ore deposits in the world. They were discovered only twenty years ago, and are controlled by the Grangesbergsbolaget. The ore contains 60 to 90% iron, and sometimes even more, and is in great demand on account of its fine quality. The export of this ore to the United States began in 1909 and increased considerably in 1910. It is especially in demand at the seaboard furnaces.

STEEL-MAKING is about to be initiated in the Transvaal, success having at last attended the efforts to secure the necessary capital for the erection of a plant to manufacture drill steel from scrap. This is regarded as a beginning perhaps of an iron and steel industry in the Transvaal, about which there has been much talk of late, but it is recognized that vast changes will have to take place in Africa before a legitimate self-supporting iron or steel trade can be profitable.

Silver-Lead Smelting

By L. S. AUSTIN

In the intermountain region of the Western States progress in the smelting of silver-lead ores (which at the same time carried more or less gold) was at first one of increasing complexity, but later rather one of elimination, that is, of simplification. In the first period the problem was a simple one. The surface ores, largely oxidized, were subjected to a reduction in smelting, yielding the recoverable lead as base-bullion. If sulphides were present on the charge, the sulphur was largely volatilized, and what little matte might have been made, was thrown away as not worth bothering with. But this condition could not last when it became necessary to treat sulphide ores. They were either put through the furnace, making matte which was heap-roasted, or were crushed, roasted, and then smelted, with the production preferably of no more than 10% of matte as computed on the weight of the total charge. Though no account may have been taken of it, many ores contained some copper which when smelted yielded copper-bearing matte. When this was present the metallurgist began to find out that cleaner slags were produced and, with increasing sulphur, less fuel was needed. Sulphides containing galena, blende, and pyrite, were at first roasted in the long-bedded reverberatory furnace at a cost of \$1.75 to \$2.50 per ton, but this was an expensive operation, and for some years a determined attempt was made to substitute the mechanical furnace, already successfully used on copper ores. But these furnaces failed because in the presence of lead, the charge, upon an incautious increase of heat, was liable to sinter and adhere to the hearth; then troubles began for the mechanically-operated rakes. Even the Brückner cylindrical roaster might, with lack of care, have its charge 'hung up,' the mass adhering to the entire interior surface of the cylinder, so that it had to be barred off. Still, with careful handling, costs could be cut in half as compared with hand-roasting, and this latter was done only for roasting of that necessary product of the blast-furnace—lead matte. To this day this is still done. The fact is, when crushed matte is roasted, it must have a high finishing heat if there is to be a proper roast, and no furnace has been so satisfactory for this purpose as a hand-operated one, where, before drawing, the charge is subject to the highest temperature of the adjacent fire.

With the introduction of pot-roasting, or blast-roasting, and especially of down-draft sintering or sinter-roasting, as the operation has been variously called, a new set of conditions arose. The plant occupied a comparatively small space, a better sintered product was obtained than with ordinary roasting, and in consequence the blast-furnace drove faster. In down-draft roasting, practically no flue-dust was made, and finally the product, when smelted, lost more sulphur through volatilization than with the old-fashioned roast. According to the patentees of the Carmichael-Bradford process, a final product, CaPbO_2 , results from the blast-roasting. This reacting upon decomposed sulphides would explain the increased sulphur loss just mentioned.

Smelting under the approved methods would therefore seem to include:

- (1) Screening all oxidized ores and sending the oversize of a $\frac{3}{8}$ -in. screen to the blast-furnace.
- (2) Crushing all sulphides intended for roasting.
- (3) Combining or bedding the fine oxidized ores with the crushed roasting ore, and by-products of the furnace, that is, with the matte after crushing, and with the flue-dust.
- (4) Giving a sinter-roast to mixture (3), and then sending it to the blast-furnace.
- (5) Catching all flue-dust and volatilized lead by means of dust-flues and a bag-house.
- (6) Remelting all base-bullion, and returning to the blast-furnace, the dry drosses containing not only lead but some copper, arsenic, and antimony.

In the earlier silver-lead smelting plants, even where sul-

phide ores were roasted, materials were handled by wheelbarrow or by tram-car, whereas, in the modern plant, mechanical handling has been substituted to a great extent. But machine handling has increased the cost of plant-equipment in such a degree as to overbalance this advantage. Thus, where formerly silver-lead smelting plants were built to cost \$2 to \$3 per yearly ton, recent methods of construction have raised the expense to as high as \$6 per ton per annum. Interest may be computed on this additional amount at 7%, and the history of plants show that in from 7 to 10 years they are in a large degree obsolete, and plant after plant has been discarded largely for this reason. Allowing a depreciation loss of 10%, it follows that 17% of the total additional charge is due to better and more modern construction. Indeed, it may be questioned whether this idea of thorough building and cheap handling has not been overdone. If an alteration is to be made, due to change in methods and improved processes, it is pretty expensive to tear up heavy foundations and retaining walls or to alter iron buildings. With side-hill construction, either expansion of plant or alterations are more expensive than those made at a level site.

If these increased costs of construction be considered to be to obtain cheaper handling only, then the comparative costs per ton of materials may be computed as follows:

	Old method.	New method.
Unloading and bedding.....	\$0.11	\$0.04
Charging to the furnaces.....	0.14	0.04
Interest and depreciation.....	0.51	1.02
	\$0.86	\$1.10

According to the above it would be actually more costly to handle material at a modern plant than in the older and simpler one. But on the other hand, the older wooden construction carried a higher fire risk, needed more current repairs, was more subject to the disadvantages of lower priced labor, and was less certain in operation.

That the fine ore, even when oxidized, should be screened out seems evident when the action of the blast upon it is studied. In the first compartments of the dust-flue will be found particles of 20-mesh material. It is true that this portion of the flue-dust contains particles of coke and limestone, but a general average will be equal to the average of the charge. It seems wise, therefore, to remove fines before smelting rather than to recover them later and to have again to handle them. On the other hand, the blast-furnace is a pretty effective screening machine. The cooled gases, by the time they reach the bag-house, are dropping their load of volatilized lead in flocculent form. As a guard against volatilization, poor working of the blast-furnace, and fine ore, the bag-house is effective. Thus, Sprague has succeeded in so effectively treating the blast-furnace gases that it needs careful observation to note that any visible smoke is escaping, even with a half-dozen furnaces in blast. A recent improvement in the bag-house consists in a new method of shaking the bags. The older way was for a man to enter the chamber, protected with a smoke helmet (such as is used in mine-rescue work), and shake down the adherent dust by hand. Now the method consists in cutting off the pressure in the chamber and so connecting to the stack as to produce a suction in the lower chamber of the bag-house. This loosens the flue-dust as the bag collapses. It is rapid and requires no hand labor.

The older way of preparing ore for use at the blast-furnace has been to layer or bed it and then to smelt each bed as though it were a single ore; but this has its drawbacks. In the first place bedding is more or less imperfectly done; then as the ore is removed the face may suddenly fall so that too much of the upper layers enter the charge. Thus are introduced into furnace-operation various irregularities which reflect themselves in poorer working and in dirty slags. The Messiter system of bedding, as used for copper ores at Cananea, offers an ideal solution to the above-named troubles. Its cost in a warm dry climate is half that as compared with a bin system, though for a northern climate housing-in would add largely to the expense of installation.

Where bins are used materials are drawn off and weighed into the charge-car, making a large unit charge, and this is the best present way of charging. It is now planned to deliver the ingredients of the charge in regulated proportions by conveying belt to the furnace. This plan will cut down charging costs and its development will be watched with much interest. Its difficulties where coarser ore is fed seem serious.

The most important work of the year has been in the working out of the sinter blast-roasting. Besides the now well-known Dwight-Lloyd down-draft machine, we find the Bellinger up-draft endless-chain machine, where to prevent the escape of flue-dust the ore is covered with a layer of crushed limestone. At the feed end of the grate and outside the roasting hood are two hoppers, one feeds the ore mixture on the bed where it is ignited, the other feeds on top of the ore a thin bed of crushed limestone or coarse ore, which serves as a filter and to hold down the fine ore from being blown away. The sintered ore is discharged outside the roasting chamber at the end opposite the feed. The Dwight-Lloyd machine is now built in 100-ton units and is giving a satisfactorily roasted and sintered product with a minimum of fine unsintered ore. No breaking up of the product is needed as in the case of pot-roasting. For success in sinter-blast roasting a suitably combined mixture is essential, one which will sinter properly and that contains 17 to 23% of sulphur, so that enough is present to give the necessary heat. The ingredients should be for galena about 8-mesh, and for the other ores about 4-mesh size. The other advantage of the continuous sinter-roast machines is that for a given capacity they occupy little space as compared with the hand reverberatory. Thus a 100-ton Dwight-Lloyd machine could be placed in a building needed for a single hand-roaster, or, say, in one-seventh of the space needed by the latter.

Australian practice with the Carmichael-Bradford process has brought out some encouraging features in blast-roasting. Three parts of concentrate, slime, or mixed concentrate and slime, are combined with gypsum which has been heated on iron plates to dehydrate it to about 50% of its contained water. These are mixed in a pug-mill with a small amount of water, and passed through a trommel to form into lumps. The partly hydrated gypsum combines with more water, and sets in hard lumps, and the lumps are further dried on a floor. To start the roasting, a shovelful of embers and a bucketful or so of chips are placed at the bottom of the pot, a gentle blast turned on, and when well lighted the granulated mixture is run in from a hopper and the blast raised to 8 to 12-oz. pressure. The converting is complete in three to four hours. Besides quick roasting but little attention is needed during the process. The plant is less expensive than the Huntington-Heberlein, and where limestone and gypsum are cheap costs less per ton.

Butte Copper Production

The production of the Anaconda and East Butte smelters in 1911 is given by *The Butte Intermountain* as below, figures being in pounds of copper.

	Anaconda.	East Butte.
January	21,600,000	1,137,882
February	20,900,000	770,746
March	21,900,000	1,156,161
April	21,500,000	1,183,636
May	21,700,000	1,235,158
June	21,850,000	1,144,767
July	21,052,000	981,310
August	22,500,000	789,101
September	21,300,000	969,224
October	21,400,000	1,107,714
November	20,850,000	*980,000
December	*21,600,000	*1,120,000
Totals	258,152,000	12,586,699

*Estimated. The East Butte also produced 402,542.81 oz. of silver and 18,177.215 oz. of gold.

Production and Prices in the California Oilfields

By J. H. G. WOLF

Production of petroleum on an extensive scale in California began with the discovery of the Kern River field near Bakersfield in 1900. The yield of all the fields was then some 3,000,000 bbl. annually; the markets were correspondingly limited, and the price per barrel to the producer averaged one dollar. The flood of oil following the opening of the Kern River field sent the production figures for Kern county alone, by 1903, to 18,000,000 bbl. annually, and the price to 20c. and less to the producer. That date and circumstance marked a new epoch. Consolidation of interests, absorption of the smaller by the larger com-

great Midway valley poured forth the flood of oil. The table and the graphic exhibits accompanying, present the status of the business in this State in lucid form. The overshadowing factor is the rate at which the stocks have accumulated. The stocks on January 1, 1910, were 21,000,000 bbl.; on November 1, 1911, 39,950,000 bbl., or an accumulated excess of 18,950,000 bbl., equivalent to 900,000 bbl. per month, or 30,000 bbl. per day. Analyzing the diagrams, Fig. 1 shows that the San Joaquin Valley fields are the dominant factor in the State's production. The Southern and the Coast fields, while

*Figures readjusted to allow for storage losses, Lakeview well losses, etc.

†All wells of State, except the 402 in Los Angeles City field and the 135 at Summerland, the yield from which combined is only about 1000 bbl. per day, and which can be considered as spent wells.

panies in some cases, and the beginning of a coöperative movement among the interests remaining independent was the logical outcome of that situation. The influence of the coöperative movement soon began to be felt; collective instead of individual bargaining with the marketers, together with the effects of the expanding uses of crude oil and the improvement of transportation facilities, sent the price back to about 50c. per barrel by 1907. That year the Independent Oil Producers' Agency (the outcome of the coöperative movement) made a two-year contract with the Associated Oil Co., one of the three marketers, at some 63c. per barrel at the well. The effect was magical; hundreds of drills were set to dropping in every part of the State, and the consequences thereof marked another epoch. When the drill of the Lakeview Oil Co. at Marieopa and near the old Sunset field, dropped through the last 'shell' on March 15, 1910, into the producing sand, it dropped into a veritable Pandora's box, the riches of which no operator, in the moments of his maddest dreams, adequately foresaw. With the opening of the box the riches escaped and spread upon the land, but elusive hope, following the legend, remained bottled up. The dreams of wealth were dissipated almost in a day; the price of crude oil at the wells dropped from 60c. to 30c. within a few months after the Lakeview and the attendant gushers up and down the

important in themselves, particularly because of the advantage of being nearer to tidewater, influence the general situation mainly as regulators of the volume of output. The field consumption of the State is some 420,000 bbl. monthly, which constant should be added to the figure for a particular month to obtain the gross output. The amount of fuel consumed in pumping the oil to tidewater is not known, but it must to some extent influence the net output to the market. The drop in output between September 1910 and February 1911 was due principally to the decline and final collapse of the great Lakeview well. The diagram shows a magnified drop in February, due to its having 10% fewer days than an average month. The recovery from March 1911 onward has been uniform and coincident with the bringing in of an increasing number of flowing wells from the deep territory of the Midway, revealed as oil-bearing by the discovery of the Lakeview. The November output (not plotted) was about the same as the two previous months. The one gratifying aspect of the overproduction situation is the manner in which shipments have increased. While shipment figures are not consumption figures, as expounders sometimes think, they are significant indicators of the same. Of the stocks carried in the State, some 20% are carried in the pipe-lines and storage at tidewater. Thus a volume

of 8,000,000 bbl. may be considered as the 'fixed' stocks. With so large a constant, improper deductions as to expansion in consumption can easily be made. The diagram must be interpreted broadly; the shipments for November were some 400,000 bbl. less than October, though it was reliably reputed that the sales in November were greater than in any month since California began producing petroleum; it is also reliably reputed that prices on San Francisco bay have advanced. Fig. 2 exhibits the unvarying rate of increase in stocks from January 1910 onward. The volume of stocks has increased, it would seem, to a figure sufficient to satisfy any ordinary demands of commerce. There is nothing appearing in the outlook to presage a change in this rate of increase. The surplus December 1 over November 1 is reported as 1,141,000 bbl.,

conditions. The first is the profits of the producer, which will place the industry on a sound business basis, and which in turn makes for stabler prices for the consumer; and the second, the conservation of the most important, if not the greatest, natural resource of California. Both are worth fighting for and winning. Without the stimulus in 1907 and 1908 of prices which gave the producer a fair profit, it is doubtful whether the extensive wild-cattling of the great West Side country (the Midway) would have been undertaken. Today the consumer has the knowledge when contracting for fuel oil, that there has been developed in the additional proved fields a supply which competent geologists estimate cannot be exhausted in 50 years. This wonderful showing is a guarantee to him of the certainty of the supply and non-fluctuating prices; it is

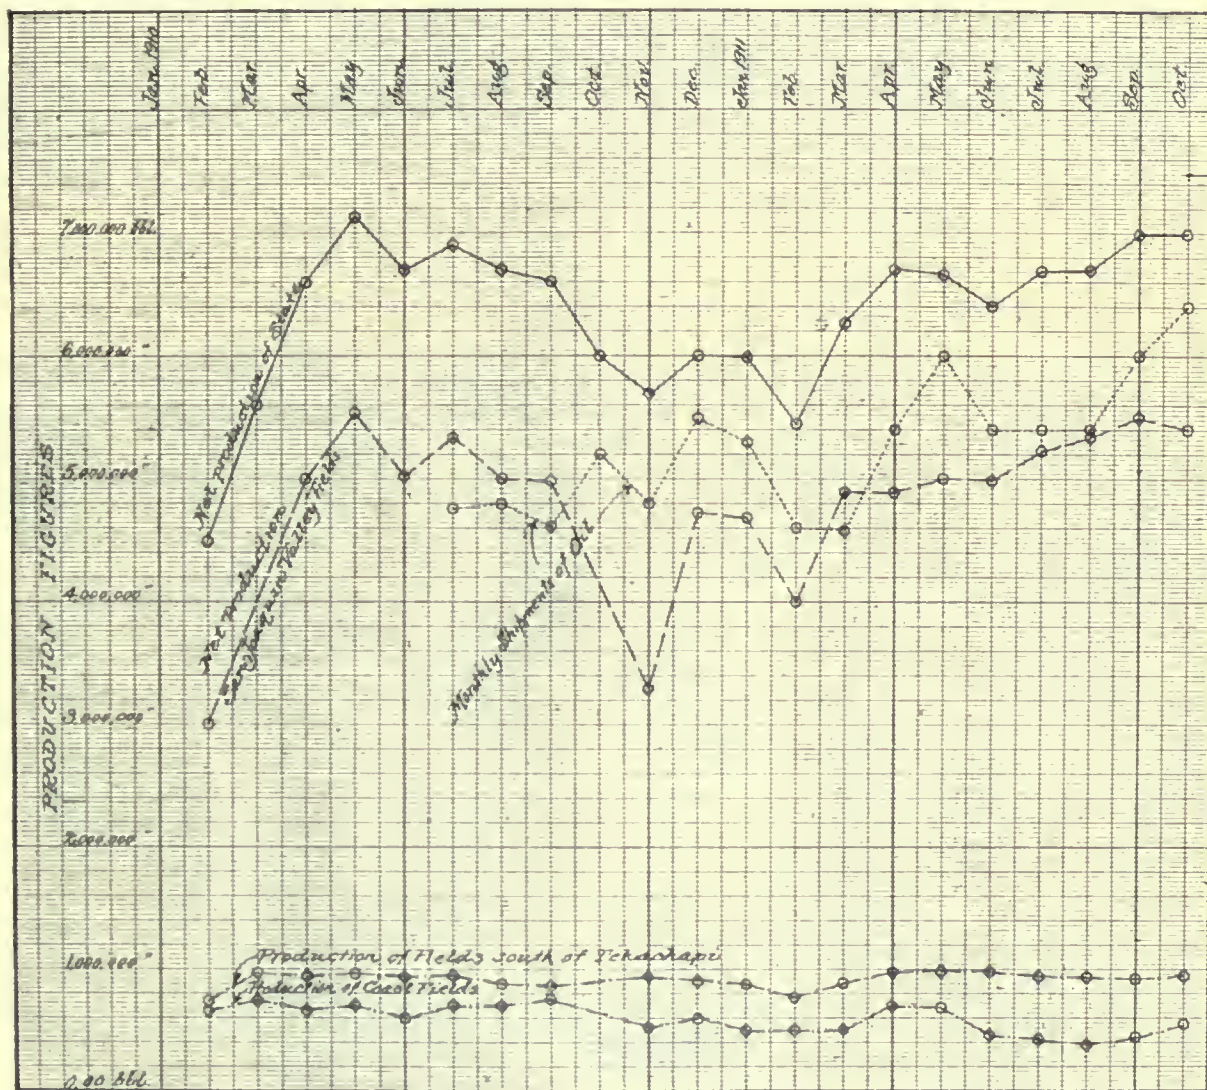

FIG. 1. NET GROSS PRODUCTION AND MONTHLY SHIPMENTS, CALIFORNIA OILFIELDS, JANUARY 1910 TO OCTOBER 1911, INCLUSIVE.

which is about the monthly surplus for the 12 months past. The returns to the producer have remained fairly constant since the break in the spring of 1910. Fig. 3 presents an important exhibit. It shows that the uniform increase in production has followed the increase in the number of producing wells, and until the rate at which new wells are being drilled and new wells are being put on the beam is decreased sensibly, there will probably be no reduction in stocks or betterment of conditions. The November figures (not plotted) of drilling show no material increase, which is helpful. The production per well per month over the State has dropped but little since July 1910, when the Lakeview had about reached its maximum, indicating unmistakably that the wells brought in since that time are heavy producers. The present yield is about 1450 bbl. per well per month, net.

There are two objects to be served in bettering present

the result largely of the coöperative effort some years ago of a handful of individual producers to improve their own condition, and who succeeded in getting a fair price for their product.

Substantial stocks are a necessary adjunct to every business. The Independent Producers' Agency, through its marketer, the Union Oil Co., has sold 60,000,000 to 70,000,000 bbl. of oil, to be delivered over a period of five years; stocks in the hands of the Agency amount to some 14,000,000 bbl., which is a comfortable surplus, but one that is a burden when prices are depressed. California supplies 36% of the crude petroleum produced in the United States and is carrying stocks aggregating 50% of its annual yield; the remaining States, producing 64% of the total yield, carry stocks of 105,000,000 bbl., or 77%. Viewed in that aspect, the volume of stocks here is not disproportionately large. The menace is the rate of increase of stocks; it

is so much in excess of the rate of expansion of sales (consumption) that there can be no hope for an early resumption of normal conditions. There is no profit in producing crude petroleum at 30¢. per barrel in this or any other State, capital and other charges properly considered, excepting from flowing wells, and an industry that cannot be conducted at a profit is not on a sound basis. To improve fundamental conditions, it appears that help might be derived in the following ways or directions: (1) The immediate cessation of active drilling in known or proved oil territory; (2) providing adequate storage facilities for the oil now upon the ground; (3) the release of all les-

highly productive territory better defined, drilling in the fields yielding only ordinary pumping wells has practically ceased. The wells now being brought in are mainly of the flowing type. This is an added menace. There are today 5401 finished oil wells, of which 4720 are actively producing, against 4320 finished wells and 3965 producing wells 14 months ago. In other words, the actual daily yield of 222,600 bbl. represents but 87% of the potential daily yield at this time. If there were a market, these idle wells would be put back on the beam. All the idle producing wells may not have the capacity of the average producing well now on the beam, but, on the

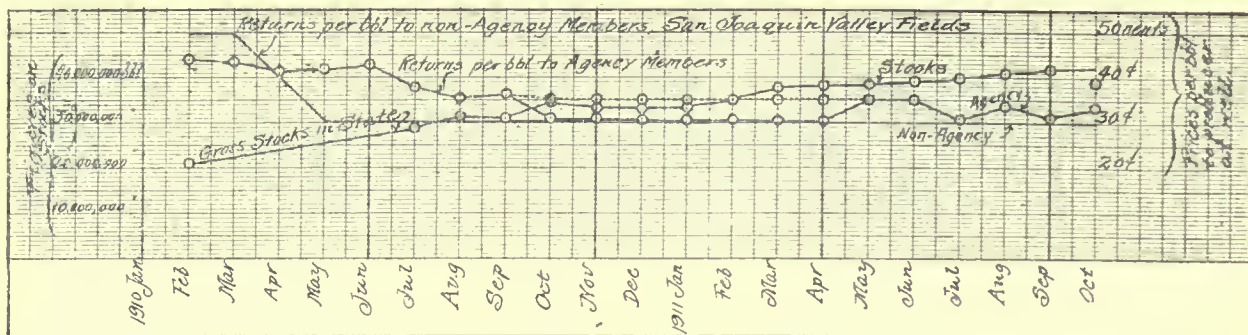

FIG. 2. VOLUME OF STOCKS IN THE STATE AND RETURNS PER BARREL TO PRODUCERS FROM AND AFTER JANUARY 1910.

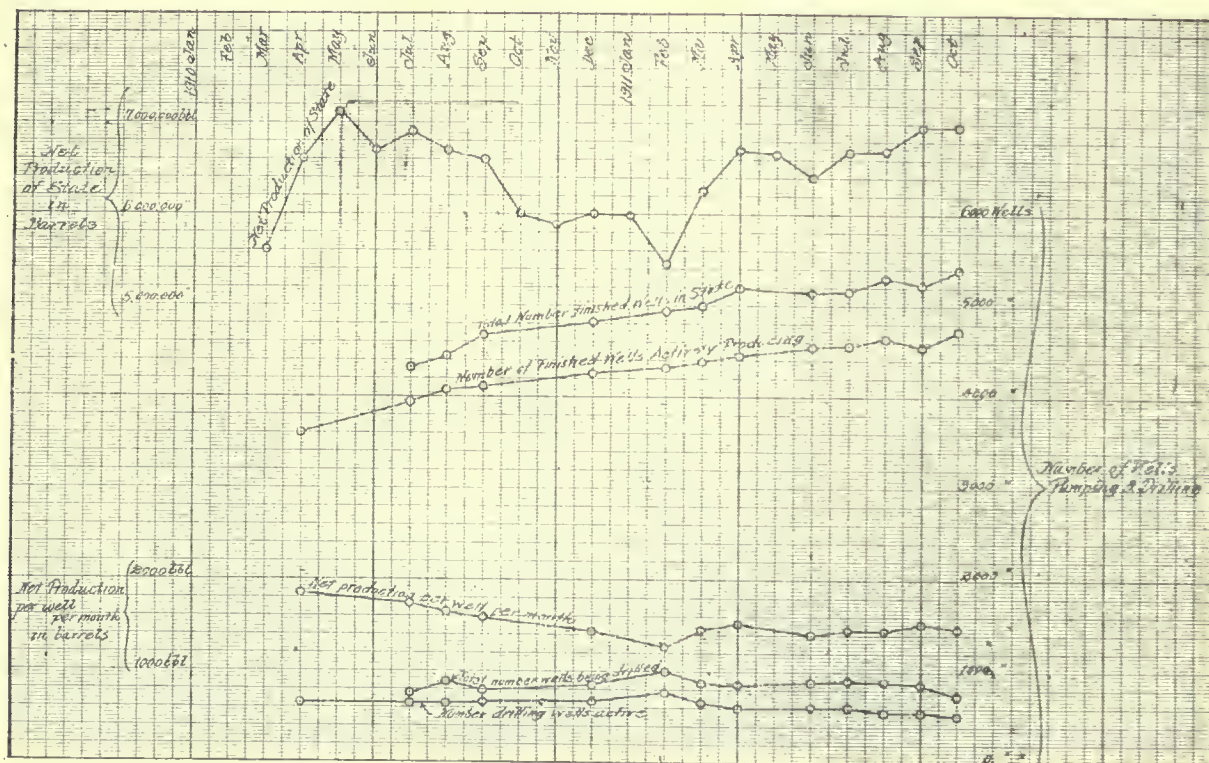

FIG. 3. NET GROSS PRODUCTION OF CALIFORNIA AS INFLUENCED BY THE NUMBER OF WELLS PRODUCING AND WELLS BEING DRILLED.

ses by the lessors from the requirement to do continuous development work, particularly in proved territory, until normal conditions are restored; (4) expansion of the sales for the product; (5) the stopping of the removal of oil being produced from lands to which the Federal Government claims title, and the lands which were withdrawn from entry and exploitation on September 27, 1909. Statistics show that on July 31, 1910, or four months after the Lakeview well was brought in, and when drilling activities accelerated by the phenomenal yield of that well, were under full swing, the number of wells being drilled was 751, of which 633 were active. On October 31, 1911, or 14 months thereafter, in the face of an accumulating excess of 1,000,000 bbl. per month, 845 wells were being drilled, of which 521 were active. It is fair to assume, too, that with the limits of the newly discovered

other hand, there are numerous capped and restrained gushers which can pour forth a flood of oil if cut loose and which might maintain the average. The present situation has this added element of danger not generally recognized. It would seem, then, that so simple a corrective measure as stopping the active drilling in proved territory is demanded by common sense and ordinary business prudence. The big factors in the producing end of the business can get together in a 'gentlemen's agreement', if in no other way, with an understanding as to new drilling. Since the term 'big factors' comes near to meaning the marketers, it is plain the small factors would, in event of any such agreement, likewise cease drilling. Mutual mistrust has to be set aside. If the marketer will stop drilling and stop buying oil for a period, the situation will correct itself

automatically. Once corrected in that manner, the measure will be used again, and the status of the business will be raised from its apparent 'extra hazardous' class to its legitimate position. As the industry is the controlling factor in the fuel problem on the Pacific, is it not time to get together?

The building of adequate storage facilities is under way. The Standard has greatly increased its field storage by building permanent reservoirs, the Associated is increasing its field storage rapidly by adding concrete-steel reservoirs, and the Independent Producers' Agency has storage measures under way which will, if effectually carried out, make its position secure and will relieve the present distressed situation of many of its individual members. Storage in steel or concrete reservoirs conserves the oil produced; the losses and wastage are enormous under present conditions.

A large percentage of operations are conducted on lands under leasehold. The owners of these lands are concerned principally in collecting royalty—oil produced at no capital outlay or risk of their own. Lessees today can with profit get concessions on their continuous drilling requirements; to do continuous development on proved ground with oil at a price less than its commercial value, is not sound business. A clause in contracts limiting drilling activities when the price at the wells is less than a figure calculated to give fair remuneration is good business for all concerned, though it is not generally used.

The expectation for expansion of sales must be based largely on the adoption of oil as fuel by the trans-Pacific shipping, by the Government, and its more general use in the Northwest. The domestic markets are quite well worked up. Sales have been pushed as far east as Ely, Nevada, in competition with Utah coal, and to Arizona and Cananea, Mexico, on the Southwest, in competition with Texas oil and New Mexico coal. California crude oil is sold as far north as the Copper river in Alaska, in competition with the vast though undeveloped coalfields nearby. The sale of oil as fuel has been pushed as widely as competitive conditions will permit; establishing the present horizon has been a levy upon the producer's livelihood.

Stopping the removal of the oil from lands in dispute would serve the immediate situation well. The courts are about to try the Government's contention that the Southern Pacific railroad has no rights to the oil under the lands patented to that company under the railway-aid acts. The deeds to the lands reserve the right to the mineral contained to the Government. The acts apparently made no such reservation, and an adjudication of rights is in order. Meanwhile, it would be most helpful if the removal of the oil were held up temporarily. A year ago the railroad was consuming in its service some 32,000 bbl. per day, which quantity was bought largely in the general market. Drilling activities in the past year, through its petroleum department, the Kern Trading & Oil Co., have resulted in a reputed output of 30,000 bbl. per day, which represents about the present daily surplus. The extent of the production from the lands withdrawn from all forms of entry or exploitation by the President on September 27, 1909, is not known. It may be considerable. The gushers or flowing wells of the Midway, the disturbing factor, are wholly upon lands considered prior to 1908 as possible oil-land only. They lie away from the 'cropping' wells, upon the flats and in the hills to the north and east. The withdrawal order came before any sensational wells were found, and includes all lands not then lawfully entered upon or occupied; hence many of the gushers are upon disputed land. The status of the operators upon the withdrawn lands is uncertain, regardless of the rights concerned, and it is not improbable that the Government will endeavor to restrain the removal of the oil pending adjudication. This will retard production until other conditions adjust themselves, which in the end will help the individual producers the more effectively. Whether or not it was lawless to proceed with drilling on the withdrawn lands, did not concern many of those who did so. Whether or not

those who respected the law and kept to their slow-pumping wells should have their production blanketed and their returns cut to a modicum of profit was immaterial, so long as more oil could be brought to the surface. The denouement of this situation is awaited with interest.

Phosphate Rock in the West

By F. B. WEEKS

Of the phosphate rock used in the Western States in 1911, 90% was mined in Idaho, Wyoming, and Utah. The production in these States was about 10,000 tons, which is practically the same as that for 1910. The entire product was obtained from the mines of Bradley Bros., in northeastern Utah near Sage, Wyoming; those of the Union Phosphate Co. at Cokeville, Wyoming, and the mines of the San Francisco Chemical Co. at Montpelier, Idaho. The Utah Chemical & Fertilizer Co. has a large area of phosphate land east of Georgetown, Idaho, but it has not yet begun shipping rock. No production is reported from Montana.

Several placer patents to phosphate lands were issued by the Government during 1911, and the policy heretofore announced by the Interior Department of granting patents, either placer or lode, to original locators who filed on the land prior to the phosphate withdrawals, has been continued. Considerable development work was done during the year preparatory to applications for patents. The question as to how the Government will dispose of the phosphate lands in the withdrawn areas is still unsettled, and there is no prospect of an early decision. There appears to be much difference of opinion among members of Congress and administrative officers in reference to the further disposal of phosphate land. It is quite certain that the phosphate lands now held under patents or mineral locations are advantageously situated with reference to transportation facilities, and the rock can be mined at low cost. These mines will therefore supply the Western market for many years, and there is no necessity for a hurried and possibly inadequate solution to the question. It may well await the result of an extended discussion of our future public land policies and the laws which will make them effective. The legal status of those who acquired mineral rights prior to the withdrawals of phosphate land is still undetermined. During the past year the question as to the rights of lode locators over prior placer locators has been before the U. S. District Courts, but no decisions have been rendered.

Geological field work of the U. S. Geological Survey during 1910 and 1911 has considerably extended the known phosphate area, and its estimate in tons has assumed almost incredible proportions. The productive area of phosphate rock in other parts of the world has been greatly extended within recent years, and there need be no apprehension of the exhaustion of the available supply.

Practically all of the phosphate rock mined in the Western States is shipped to San Francisco and Los Angeles and manufactured into acid phosphate and mixed to make complete fertilizers. About 20,000 tons of fertilizer was sold during 1911, nearly all of which was used in California. With the exception of 1500 tons shipped from Japan, the entire product was manufactured in California. The outlook for a considerable increase in the near future in the use of phosphate rock in the West is not, at present, encouraging. Such increase depends largely on the practical demonstration of immediate improvement in crop returns as the result of the use of fertilizers through Government or commercial agencies. What may be done through foreign shipments to further the sale of phosphate rock is problematical. Existing transportation rates to the Pacific coast are prohibitive so far as foreign markets are concerned. At present, 70% rock is worth about \$7 per ton on the seaboard. The freight rate from the phosphate region is \$1.20 per ton to San Francisco, and \$5 to Los Angeles. This leaves a small margin to cover mining, transportation, and loading charges at the mines.

Metallurgy of Copper During 1911

By THOMAS T. READ

Progress in the metallurgy of copper during 1911 has been by advances along lines already established rather than by new departures. The situation in regard to blast-furnace smelting has not materially changed during the year, and there is little to record beyond attempts to apply the use of liquid fuel to the blast-furnace. Reverberatory smelting naturally grows in importance as the amount of copper produced from low-grade ores which have been subjected to wet concentration continues to increase. Roasting, agglomeration of fine ore and fine-dust, the converting of matte, the handling of fume, and the leaching of copper ores, have all been objects of study, and substantial progress must be recorded. New construction sufficient to produce many million pounds of copper has been either completed or initiated during the year.

The use of liquid fuel for blast-furnace smelting has often been proposed, and supplementary oil-jets have often been used to thaw out tuyeres and to warm up cold portions of the hearth. But its employment as the sole source of heat offers obvious difficulties, and metallurgists have been loth to fly to evils that they knew not of. The increasingly general use of fuel-oil and the present availability of a plentiful supply at low cost in many areas has refused to let the matter rest, however. The problem has been attacked from both sides; by the machinery manufacturers and by operators. The Colorado Iron Works Co., of Denver, has devised a 100-ton round water-jacketed blast-furnace, designed to employ only oil as a fuel. The oil is burned in a heat-insulated outer combustion chamber and the products of combustion led directly into the shaft-furnace immediately below the tuyeres. The water-jackets are run hot, allowing the excess heat to escape as steam, rather than as hot water, thus doing away with the launders. The furnace is provided with gas taps and pyrometers to aid in the control of the smelting operation. It is claimed that with coke at \$12 per ton and fuel-oil at \$1.25 per barrel, the relative fuel requirements to produce 100,000,000 B.t.u. are as \$52.80 to \$21.05, and it is further claimed that the reducing action of this type of furnace is under better control.

During the year a demonstration of blast-furnace smelting with oil was made by Thomas Kiddie at the plant of the Dominion Oil Smelting Co., Ltd., at Van Anda, Texada island, British Columbia. The type of furnace employed is not described, but presumably was of Mr. Kiddie's design. The test was brief, lasting only part of one day, but in his report to the directors, Mr. Kiddie claims that the furnace smelted at the rate of 110 tons of charge per day, with a fuel consumption of 14.6 gal. of oil per ton of material smelted, corresponding to a fuel cost of 44c. per ton. It should be noted, however, that this is little more than an estimate, a total of 217 gal. of oil having been used, 60 gal. of which was considered to have been used in heating up the furnace. Mr. Kiddie recommended certain changes which he believes will lead to a reduction of the fuel cost to 30 or 35c. per ton. The results of such experimental runs will be regarded with interest, but the attitude of metallurgists generally toward the use of liquid fuel in the blast-furnace is much like that toward aeroplanes, a belief in eventual successful employment and usefulness, under proper conditions, coupled with a disposition to allow those so disposed to do the development work. Blast-furnace smelting of the ordinary kind is exhaustively discussed by Peters¹ in his 'Practice of Copper Smelting,' which appeared early in the year, and no further comment is here required.

Roasting of lump ore is now practically a thing of the past, and the roasting of fine ore has practically crystallized along two general lines, ordinary roasting and roasting to produce sinter. For the former the use of the McDougall furnace is wellnigh universal. The latter has recently been

exhaustively discussed by Hofman², and but little comment need be added. Blast-roasting, so popular for the treatment of lead ore, has not proved so successful for the treatment of copper ores, and in some cases where it has been tried has later been abandoned. It is in successful use³ at the Ashio plant of the Ashio smelter of the Furukawa Mining Co. But, as pointed out by Peters, blast-roasting of copper ores may involve either the removal of as much of the sulphur as possible, or as little as possible, according to circumstances, and the problem of roast-agglomeration is therefore more complex than appears at first sight. It may be said generally that where all the ore must be subjected to a preliminary wet concentration it is hopeless to attempt to so agglomerate the fine concentrate, either by blast-roasting or briquetting, that endless trouble will not arise in blast-furnace smelting, and present practice is to use reverberatory smelting in all such cases. Where, as at Ashio, labor is so cheap that a considerable proportion of lump ore can be sorted out to advantage, it may readily be possible to agglomerate enough of the fine concentrate to bring the total fine ore in the blast-furnace within working limits, and thus reap the advantage of lower smelting costs. The various types of sintering machines, such as the Dwight-Lloyd, from which so much was hoped, have not come up to expectations in copper practice, though, curiously enough, they have found an unexpected application in the sintering of fine iron ores. This well exhibits the status of the case: the machines are efficient enough in operation, but the conditions in copper metallurgy are not well suited to them.

L. D. Ricketts, who continues to set an example of generous disclosure of information of value that might well be imitated by fellow metallurgists, has given⁴ the cost of calcining in McDougall furnaces at Cananea. "I give below costs and other information for the six months from February to July 1911, inclusive, during which both reverberatory furnaces have been in operation. The calcining expense in the McDougalls includes all costs from the time the railway delivered the material to be calcined to the bins, until the calcine is delivered at the reverberatory furnaces. We have dispensed with the tramway from the concentrate bins to the top of the McDougall furnaces, and have introduced a bedding system which gives room for two beds of self-fluxing charge of 3000 tons each. The ore is received on belts from the railway bins, sampled on its way to the beds, and is bedded, reclaimed and conveyed by belt to hoppers over the McDougalls which we have recently installed and which give storage sufficient to run the furnaces for 18 hours. As a consequence, reclaiming has to be done on but one shift. The costs were as shown in the table below."

CANAEA CALCINING COSTS, FEBRUARY TO JULY, 1911

	TONNAGE CALCINED		Per cent of total.
	Dry tons.		
Concentrate	32,929		76.08

At the Steptoe Valley smelter, at McGill, the limestone required for fluxing is not added in the McDougalls, as the sulphur in the concentrate is not high enough to give sufficient excess heat for warming the limestone. At the Tooole plant, on the other hand, screened silicious ore is added upon the fifth hearth of the McDougalls, this difference in practice being due to a 3% higher sulphur content in the Tooole roaster charge. It should be noted that this addition brings the heat close to the working margin, so that in the case of temporary shut-downs it is necessary to employ a few shovelfuls of coal to bring the roaster back to its normal working temperature. This well illustrates the close margin of economy upon which modern smelting operations are conducted.

Progress in reverberatory smelting during the year chiefly centres about the increasing use of oil-firing, which has been adopted at the Steptoe smelter, following its use at Cananea and elsewhere. It should be noted that the new Tooole plant retains coal-firing, as this illustrates the essential feature of the use of liquid fuel. The Steptoe smelter is at McGill, Nevada, approximately midway between the sources of supply of fuel-oil and coal, while the Tooole plant is near the coalfields and distant from the oilfields. Fuel-oil is worth about 40c. per barrel at the wells, and Wyoming and Utah coal approximately \$1.50 per ton at the mine; upon the usual basis of reckoning of 3½ bbl. of oil as equivalent to 1 ton of coal, it is evident that the question of desirability of use comes down to a comparison of freight charges, though this is influenced by other considerations. At the Steptoe, for example, some difficulty was experienced in keeping the furnaces up to the temperature necessary to smelt a rather infusible charge, until oil-firing was employed, when the difficulty disappeared. Oil-firing, therefore, is not a panacea, but a valuable method which will find application where the conditions favor its use.

The general features of reverberatory smelting have been so fully discussed by Peters in the volume already mentioned that only a few supplementary notes need be made. The furnaces at the Steptoe are 120 ft. 10 in. long, due to the removal of the coal grates, and work well. At Cananea 20-in. arch brick are now employed on the furnaces throughout. The waste-heat boilers should be of a type which permits easy cleaning; at Cananea this is expeditiously done by the use of a jet of compressed air to blow the fume off the tubes of the economizers; this is done daily and less than an hour is required to clean four economizers. Oil-burners for reverberatory work apparently continue to offer scope for improvement.

The cost of reverberatory smelting at Cananea has been discussed by Mr. Ricketts,⁴ and his figures are given below. It should be remarked, however, that cost data are only useful as a general guide unless accompanied by copious commentary regarding methods of computation of tonnage, cost, distribution of cost, and all the other conditioning circumstances. For example, if cold seconds are included as part of the tonnage smelted a material difference is made in the costs per ton. Liquid converter slag should not be regarded as a part of the charge, for the general opinion now is that its excess iron is of little or no use in slag formation in the reverberatory. In the light of the experiments by G. B. Lee and F. A. Rutherford at the Copper Queen, Mr. Ricketts has suggested that by feeding flue-dust and hot converter slag into a device resembling a concrete mixer the two undesirable products could be converted into a single desirable one. By screening out the lumps and returning the dust to the mixer a useful addition to the charge would be secured, but the question of operating cost is one to which no definite answer can yet be made.

The use of the basic-lined converter bids fair to become universal. C. B. Neel has discussed⁵ some of the general features of recent progress in this work in a paper of much interest upon which only considerations of space prevent extensive comment. The Pierce & Smith type of converter is coming into wide use for its large capacity and convenient shape, with the modification of the use of a central mouth rather than at the end, as this gives a better distribution of the gases inside and of the flux added. The

⁴Eng. & Min. Jour., April 8, 1911, p. 707.

flux, which was at first preheated, is now commonly added cold. The Day process, of blowing silicious slime into the converter through one of the tuyeres, is now in use at Cananea. I suggested this method to my colleagues in 1904, but was unable to test the method experimentally; doubtless it has also occurred to many others, it remaining to Mr. Day to make successful application of it. The usual basic converter has a capacity of 65 tons of blister copper, about 30 tons being the usual charge finished. The high percentage of working time (88, according to Neel) very materially affects the conduct of operations in the converter house, and the crane, which is kept so busy in an acid-converter plant, stands idle much of the time. This is accentuated by the use of casting machines for handling the blister copper and the pouring of the slag into chilling pans which are drawn to the slag bins, as at Garfield, so that it begins to seem probable that in future plants it may be possible to do away with the heavy and expensive crane and substitute some other device. It is to be hoped that before the end of another year more definite data regarding this subject may be available than at present.

The problem of smelter fume received an accentuated interest during the year by the closing by injunction of the Bully Hill and Balaklala smelters in Shasta county, California, and the procuring of an injunction against the Mason Valley smelter at Wabuska, Nevada, before it had been completed. On the other hand, the United States Circuit Court of Appeals, in the 'smoke suits' against the Washoe and Anaconda plants, upheld the decision of the Master of Chancery and the trial judge that the damage done by these plants did not warrant the issuance of an injunction. The Mammoth plant, in Shasta county, continues to operate, though under surveillance, and the Washoe and Anaconda plants still have the suit of the Federal Government, alleging damage to a National forest, pending against them. In the latter case a committee, consisting of L. D. Ricketts, J. A. Holmes, and J. H. Hammond, has been appointed to arbitrate the matter, the understanding being that if the smelters put in force the recommendations of the committee the Government will not press the suit. The general features of the smelter-fume problem have recently been so admirably discussed by Herbert Lang⁶ that only a few points of interest will be made here. The solid particles in smelter fume can be removed effectively upon a practicable working scale by either the Cottrell⁷ or bag-house⁸ process, but the SO₂ content is more of a problem. The Tennessee Copper Co. is engaged in converting it into H₂SO₄, but this is not of universal applicability for a number of reasons, the chief of which are that markets for the acid thus produced are commonly lacking, and the concentration of the gases in SO₂ is frequently lower than desirable in acid manufacture. Several other methods are commonly employed. The use of tall chimneys to lift the gases so high into the air that they will be diluted before coming into contact with vegetation may be supplemented or replaced by direct dilution by blowing air into the base of the stack. In the former the initial cost is high; in the latter, operating costs are high. In Germany the Wieslenius stack is used to produce vortex currents in the escaping gases, with the idea of aiding dilution by the surrounding air. Young⁹ has proposed the reduction of the SO₂ to S, using crude oil, with calcium sulphite as an intermediary, but the process is as yet only in the experimental stage. At the Ashio plant³ the Asano process in use there, is claimed to neutralize the SO₂ as well as the SO₃, but full details are not available. As long as the principle is held to that a smelter may not commit a nuisance, trouble may be expected. But the decision in the Montana cases that the damage was not sufficient to warrant the issuance of an injunction is a hopeful one, as is the decision of the trial judge in the suit against Rathberger & Gerber of New York City, for committing a nuisance. In this case the court held that the business of the defendants was a neces-

sary one to the community, that it was necessary to carry it on within the city, and that as the odors complained of were not detrimental to health, but only unpleasant, the issuance of an injunction was not warranted.

The great importance which the mining of low-grade deposits has assumed, and the necessarily large losses in wet methods of concentration, has greatly stimulated the investigation of leaching methods. The most important result of such investigations that has been disclosed is the announced intention of the Braden Copper Co. to construct a leaching plant at its mine in Chile. According to Pope Yeatman,¹⁰ the consulting engineer, this plant will consist of 1 Wedge furnace, with acid tower, and accessories, 3 leaching-vats, 3 settling-vats, 9 solution tanks, and a precipitation plant of a capacity of 10 tons of cathode copper per day. It is thought that by this method copper can be produced at a cost of 7 or 6³/₄¢. per pound; the low cost of electric power being a great advantage. Other companies have studied the problem, and by next year I shall doubtless be able to record substantial progress and to cite the results of actual operation. W. L. Austin has published¹¹ during the year a series of articles, discussing leaching methods in great detail, but the general appreciation of these was somewhat shaken by Mr. Austin's securing, during the year, a patent upon methods of leaching copper ores in place that have been widely known and used for many years.

Below is given an estimate of the total copper production for 1911 by companies in the United States, according to Hayden, Stone & Company.

ESTIMATED PRODUCTION

	Pounds.
Almceek	15,000,000
Allouez	4,800,000
Anaconda	225,000,000
British Columbia	10,000,000
Calumet & Arizona.....	50,000,000
Calumet & Hecla.....	75,500,000
Chino	*30,000,000
Copper Range	31,000,000
East Butte	12,000,000
Greene-Cananea	45,600,000
Isle Royale	7,200,000
Miami	*38,000,000
Mohawk	11,800,000
Nevada Consolidated	62,300,000
North Butte	25,000,000
Old Dominion	25,000,000
Osceola	18,200,000
Phelps, Dodge & Co.....	132,000,000
Quincy	22,500,000
Ray Consolidated	*80,000,000
Shannon	14,500,000
Superior Copper	3,200,000
Tamarack	7,500,000
Tennessee	12,500,000
Utah Consolidated	8,000,000
Utah Copper	95,000,000
Wolverine	9,700,000

*Estimated total capacity.

Considerations of space forbid reference to many details of mechanical equipment. The Messiter electric weigher appears to have successfully solved the problem of keeping an accurate and continuous record of the weight of the mill feed, and is already coming into extensive use. The handling and feeding of ore and concentrate at Cananea, is elsewhere referred to by L. S. Austin, and is of so much interest that it is hoped to make it the basis of a later separate article. The number of plants where extensive new construction was installed or completed during the year was unusually large. The Tooele smelter of the International Smelting & Refining Co., was blown in during 1910, but construction has been in progress this year, though chiefly confined to the two new lead stacks, now in process

of construction. This plant has five 19 by 102-ft. reverberatory furnaces, and has a capacity of 1500 tons per day. The plant of the British Columbia Copper Co., at Greenwood, was built upon the site of a former plant, the time required for reconstruction being five months. This plant has two 48 by 360-in. blast-furnaces, and one 48 by 240-in., having a smelting capacity of 2400 tons per day. The Ray Consolidated Copper Co. had a 1600-ton smelting plant under construction at Hayden, Arizona, but arrangements have recently been made by which this plant has been transferred to the American Smelting & Refining Co., and the new scope of work has necessitated some changes in design. This plant should be in operation early in 1912. The Mason Valley Mines Co. smelter, at Wabuska, Nevada, has two 42 by 300-in. blast-furnaces. The ground for this plant was broken late in 1910, and it was expected to blow

in late in December 1911. At the Braden mine, in Chile, a 44 by 180-in. blast-furnace is under construction, and provision has been made for two more, if they are found necessary. The Copper Creek Mining Co. has under construction at Copper Creek, Graham county, Arizona, a 75-ton matting furnace and a 75-ton reverberatory furnace. The most important new construction now on foot is the new plant of the Arizona Copper Co., at Clifton, Arizona. Full details of the design are not yet available, but the plant will handle approximately 1,000,000 tons of ore per year, in reverberatory-furnaces. L. D. Ricketts is consulting engineer. The following table, revised from one published in 'Mineral Resources of the United States for 1910,' by B. S. Butler, may be of interest. It should be noted that the list includes only plants which treat material derived from the United States.

Cost of Developing Public Coal Lands

By JAMES DOUGLAS

*In any revision of the coal-land laws, three questions will have to be considered: (1) The quantity which should be allotted to a single entryman or corporation; (2) the terms under which the Government should part with its coal resources, whether by out and out sale, by lease, or on payment of a royalty; (3) the price which should be paid by a purchaser, a renter, or a worker on royalty. The decision of these questions is more or less interdependent. If a certain amount of coal must be secured in advance to warrant the expenditure of the capital necessary to mine the coal, and to handle it as coal or coke commercially when brought to the surface, and if this outlay is to be repaid, with a reasonable rate of profit to cover interest and risk, the operator must start with the prospect of a certain minimum supply of coal. What that acreage should be depends upon the size of the beds, and the initial outlay to utilize to the best advantage the property. In the following estimate I assume that 50% should be deducted from the estimated coal content of any given area of coal land, in determining its value, and that 10,000 acres, or 40 years' supply at 1,000,000 tons per annum, is the minimum which should be allowed to a corporation willing to erect safe and economical works and equip its mines with every known safety appliance.

The original outlay includes the cost of the surface equipment, which in the West, where the Government coal lands lie, must be costly if it is to be efficient. Based upon experience at Dawson, New Mexico, the following estimates of the value of coal land, based on one acre of land containing 8000 tons of coal, may be made:

10,000 acres land containing.....	80,000,000 tons coal	
Deduct 50% for risk of mining, land will yield	40,000,000 tons coal	
Net yield per acre.....	4,000 tons coal	
Royalty per ton	8c.	
Royalty per acre	\$320	
Number of tons mined per year.....	1,000,000 tons	
Years to exhaust	40	
		Per
	Total.	ton coal.
10,000 acres, at \$320 per acre.....	\$3,200,000	8.00c.
Cost of plant.....	1,979,264	4.94c.
Interest on plant investment, at 5% per annum, equals \$98,963 per year for 40 years	3,958,520	9.90c.
Total cost	\$9,137,784	22.84c.
Payment of 10,000 acres in advance.		
One dollar compounded at 6% per annum for 40 years	\$10.29	
Royalty of \$320 ÷ \$10.29 equals present worth per acre	31.10	
		Per
	Total.	ton coal.
10,000 acres, at \$31.10 per acre.....	\$ 311,000	0.78c.
Cost of plant	1,979,264	4.94c.
Interest on plant investment, at 5% per annum, equals \$98,963 per year for 40 years	3,958,520	9.90c.
Total cost	\$6,248,784	15.62c.

The value of coal in situ may be assumed to be determined by the royalty demanded in any given district for coal to be extracted. In Colorado, uncomplicated by store licenses, and so forth, this is about 8c. per ton. If, therefore, an acre in the Trinidad district yields on an average 8000 tons of coal, and the royalty is 8c. per ton, the gross value of the coal in the ground is \$640 per acre. If the coal were sold out and out, the compound interest calcu-

lated on the price and the number of years necessary to work out an area large enough to return the purchaser a fair remuneration for his investment, compensation for his risk, and profits on the enterprise as a business venture, must be deducted.

In determining the cost of coal, the fixed charges (in this case estimated at 15.62c. per ton) should be taken into account as well as the operating charges. Inasmuch as the plant has to be maintained in perfect working order until the exhaustion of the mines, it seems to me that the cost, as well as the interest on the cost, generally represented by interest on a bonded debt, should be included in the fixed charges. This certainly should be done, unless it is extinguished by a sinking fund during the life of the mine. Mining costs are likely to be more rather than less in the future, because the mines must be deeper and greater precautions must be taken to insure safety for the men.

If the Government should lease the coal, reserving the surface rights, and the same requirements as to initial outlay were either imposed or voluntarily acquiesced in, the rental being a mere annual payment and not imposed on the producer in advance, would be calculated on the acreage value of the coal, exclusive of the deductions for discount. But in considering the other alternatives, such as allowing the coal to be mined on royalty or rental, objections may be raised against both systems. If 8c. per ton be a fair valuation of coal in the ground, the Government would seemingly get all it was entitled to by accepting that amount; but under this system the miner has every inducement to mine cheaply and thus wastefully, and to rob the mine of its best and more profitable coal.

Under the rental system, which could be based on the calculation of the coal in a given area, less the deductions made above, the lessee, as he approached the period of exhaustion, would be paying an exorbitant figure on the balance of the value and would be inclined to evade payment.

Would not a fair system be to charge a small rental on the total area and a reduced royalty on the coal extracted? Assuming 10,000 acres to be the required area and 8c. per ton to be a fair royalty, would not a rental of, say \$1 per acre on the gross acreage, or say \$10,000 per annum, and 4 or 5c. per ton royalty, be equitable? This would secure to the miner his necessary reserves and give to the Government the value of the coal in place.

The above suggestions are thrown out as subjects for discussion; but the conclusion forces itself strongly on my conviction that if a satisfactory revision of our land laws is to be reached, the farmer, the miner, the lumberman, and the banker must be consulted before the politician acts. The coal miner alone knows the conditions and restrictions under which coal can be extracted with safety to the workman, with profit to the operator, and justice to the public; the metal miner and the mining engineer alone appreciate the impossibility of literally living up to the letter of the old mining law, and the lumberman is certainly entitled to be heard before such sweeping judgments are passed upon him as we have heard pronounced of late years. Representatives of all the interests who actually occupy the public lands should sit upon a committee to suggest revision of the laws affecting the sale and the use of the public lands after sale, if such amended laws are to be practicably applicable.

Coal Output in 1911

Coal production in the United States in 1911 is estimated by E. W. Parker, of the United States Geological Survey, to have amounted to 490,000,000 tons. This is less by 11,000,000 tons than in 1910. Of the total, 400,000,000 tons was bituminous coal. The year was one of low prices, overproduction, and extremely unsatisfactory business.

*Portion of an address delivered before the American Mining Congress at Chicago.

Proposed Revision of Alaskan Mining Laws

By F. LYNWOOD GARRISON

In the late summer of 1911 the secretary of the Mining and Metallurgical Society, W. R. Ingalls, received a request from the Committee on Mines and Mining of the House of Representatives at Washington, asking for suggestions relative to revision of the mining laws of Alaska. As it was desirable to have these data in time for the assembling of Congress in December, the secretary referred the matter to the Philadelphia section of the Society, knowing that among its members were some of the ablest coal-mining engineers in the world. The Philadelphia section held several meetings during September and October for the purpose of considering the matter. The outcome of the consequent discussion was a report prepared by a committee consisting of Eli T. Conner, William Griffith, R. H. Sanders, and myself. This report was later approved by the Philadelphia members and, after discussion by a committee of the Council of the Society, submitted for vote of all the members in the following form, in which is embodied a number of minor changes from the original draft:

1. It is essential for the proper development of Alaska that its coalfields be opened for commercial use without further delay.

2. There are now known to exist but two relatively small fields containing high-grade naval fuel, and inasmuch as the Government now possesses no original source of such supply on the Pacific Coast, it is desirable, in the interests of national defense, that a selected area of these fields be held and operated under the direct control of the Government.

3. All rights which have accrued legally under statutes heretofore existing should be recognized.

4. If it be decided by the Congress that it is to the best interests of public welfare that coal lands in Alaska be leased, we recommend that the following conditions should be embodied in the leases: (A) These leases should be made for all the coal in the ground; (B) The royalty should be low and based on percentage of selling price of the coal at the mines; (C) The minimum annual production upon which royalty is to be paid should be nominal for the first two or three years after the execution of the lease, in order to permit and encourage the installation of efficient and durable equipment, after that period the minimum production upon which the royalty should be paid should increase more rapidly than the area increases (for example; the minimum production upon which royalty should be paid on a tract of 5000 acres should be several times more per acre than for 1000 acres)—such a plan would prevent the tying up of large areas of undeveloped coal territory; (D) A due-diligence and forfeiture clause to effect continuous work should be included in the lease; (E) Leasehold in coal lands should include all necessary timber, mining, and surface rights; (F) Leases should not be given for less than 40 acres, and in shape should be rectangular, their boundaries being east and west and north and south, and after the system of public surveys has been extended to Alaska and the land applied for is in a surveyed township, the unit areas of a lease should be those established by the Government survey as subdivisions of the sections; (G) The tract of land embraced within a single lease should not be more than three times as long as its width.

5. It should be clearly recognized as a basic principle that the value to the Nation of coal-lands in Alaska lies more in their use for industrial, commercial, and naval purposes than in the royalties to be derived therefrom, and it is desirable that the revenue obtained from coal royalties inure to the benefit of the Territory.

The Secretary of the Interior, W. L. Fisher, in his address before the American Mining Congress at Chicago, October 17, 1911, evidently thought well of the conclusions

of the Pennsylvania engineers, for he added them verbatim to his address, which was afterward published by the U. S. Bureau of Mines, in Bulletin No. 36. The committee of the Philadelphia section, in carefully considering all the best available information regarding Alaskan conditions, came to the conclusion that the extent and value of the coalfields in that great domain had been unwittingly exaggerated, and that the public had a false notion as to their worth. The beds and seams are not only much crushed and disturbed, but the average quality and grade of the coal is distinctly inferior to that of Pennsylvania and West Virginia. It is true the Bering River and Matanuska fields contain some relatively small areas of high-grade coal, both anthracite and bituminous, but the extent, depth, and uniformity of these beds is absolutely unknown at the present time. Politics has befogged the whole question; mistaken deductions of geologists, unchecked and unrevised by any competent mining engineer, have been rushed into the print by the sensational press

COALFIELDS OF ALASKA. (After U. S. Geological Survey.)

under the banner of 'Conservation', until the very word has become offensive in some quarters, whereas with sensible people it should be a synonym for foresight and common sense. The truth is the mining and mineral laws of the whole United States are antiquated and need revision, and real conservation may be best accomplished in that way. Alaska is a good place to begin, although it is perfectly true, as M. L. Requa has pointed out,¹ that it will probably be many years before the coal of Alaska can be assured of a market outside of local demand; certainly at least not until the superabundant supply of California oil is greatly reduced. One exception in regard to this statement must be noted, that is, in regard to fuel for the Navy. Unless fuel oil comes to be used almost exclusively on the war-vessels in Pacific Coast waters, the Government has no original source of supply of suitable fuel except certain small areas in the Bering River and Matanuska fields.

The suggestion that the Government open and operate these fields for Naval purposes and to supply a limited outside demand, makes evident some differences of opinion.

¹Mining and Scientific Press, November 18, 1911.

That the Government is justified, under the peculiar circumstances indicated, not only in opening collieries, but in building railways to bring the coal to market, was the view of the committees and others concerned in this discussion. Surely no corporation or individual would be justified in making such a large investment as is necessary under the present conditions, even after new and satisfactory mining laws were enacted. To open the coal would be an exceedingly expensive undertaking and should be part of a greater plan for development by building of a through trunk line of railway from the coast to the upper Yukon. In the present undeveloped and unsettled state of Alaska, this can only be done by the Government; the climatic and physical conditions are too uninviting to tempt private enterprise. At best the profits of such an undertaking will be remote, though probably sure in the end; individuals or a corporation could hardly afford to wait perhaps fifty years for an adequate return upon their investment, whereas half a century is not a long span in the life of a nation. This, if you like, is paternalism, but it is sometimes necessary for governments to be paternal and take the initiative when it is desired to make the waste places of the earth blossom and two blades of grass grow where there was before but one. In other words, without Federal aid, the development of Alaska is certain to be painfully slow, and probably would be effected only with great waste of capital and effort.

The leasing system advocated by the Mining and Metallurgical Society may at first sight appear objectionable to some Western miners and mine-owners, they being generally unaccustomed to the idea. It may not always be realized that the plan proposed by the Mining and Metallurgical Society for all the coal in the ground is in reality a sale as far as the coal is concerned, since no time limit is set. An operator, knowing he has a large tonnage of coal to depend upon, may take his own time in mining it, and hence is likely to equip his property with substantial and enduring machinery and buildings, and lay out his underground work in the best manner, feeling sure that in the end it will be most economical and conducive to efficiency and preventive of waste. Another advantage of such a lease is that no large payment of money is necessary at the outset in order to acquire title from the Government. The price of the property, or rather the coal, is represented by the royalty, whose payment is an annual increment of the operating cost, depending upon the quantity of the coal taken out. The royalty rate should be small, and in such a case will hardly be felt by the operator; no amortization charge for his investment other than for equipment will be necessary on the part of the operator, yet the Government will be receiving a fair and just compensation for the public's property, and the feeling that it is giving away for nothing valuable public domain need not be entertained. Similar leasing systems have existed for years in many foreign countries, and have been, on the whole, found to be most satisfactory. It is, in my opinion, the only logical system of acquiring title to public mineral lands of all kinds; provided, of course, the regulations affecting it are based upon sound and liberal business principles. They should obviously be conditioned upon the character of the risk the lessee assumes. Thus, for example, the hazard is much greater in gold mining or drilling for oil than in equipping and operating the colliery upon a well defined coal bed. It is perhaps needless to point out the grave defects in our present archaic mining laws. In some respects they were good for the country fifty years ago, but the statute (Sec. 2322) giving extralateral rights to the locator or owner of the surface has never been and never can be anything but an ignorant and litigious enactment, a reflection upon our national intelligence and practical good sense.

Mr. Fisher's views on the Alaska coal question, which presumably reflect those of the Administration, are apparently set forth in the Chicago address above mentioned.² In this document he advocates the building and operating by the Government of railways in Alaska. The physical

and climatic conditions of this vast Territory are, on the whole, so adverse, that it is highly improbable private enterprise will venture unaided into such undertakings for many years to come. But it will be argued, has not private enterprise already built 195 miles of railroad over river and glacier from Cordova to Kennicott, on the Chitina river? This is true, and it is likewise true this railway cost its builders about twenty millions of dollars. The question why it was ever built may perhaps be best answered by those responsible for its construction. Supposedly it was intended chiefly as an outlet for the Bonanza copper deposits at Kennicott owned by the same interests, and for whatever incidental business might be obtained by the development of neighboring mineral properties. It has been stated, however, that the Bonanza is but a "third-class property, a sort of copper-plated gold brick, in that an interior core of limestone is surrounded by phenomenally high-grade bornite and copper glance, and that no competent mining man who has visited this property ever has estimated the amount of ore developed and safely inferred as capable of yielding more than 100,000,000 lb. of finished copper; a total production equivalent to only one year's maximum output by any one of the six leading copper mines of the world." "The gross value of all the copper contained in the Bonanza mine, taking the outside estimate of tonnage, is considerably less than the lowest estimate of cost of this railway, and the net profits derivable from the Bonanza mine, cannot, by the most liberal figuring, be estimated at more than \$4,000,000 to \$5,000,000."³ Assuming this statement to be correct—but which I personally doubt—it is difficult to understand how hard-headed, experienced business men can be credited with the folly of spending this large sum for a railway that has no assured traffic. It has been suggested this may be a deep-laid scheme to sell the railway to the Government as part of a national trunk-line project to the upper Yukon river. But, as has been pointed out, it would be much better, in such event, that the Government begin this trunk line or continue the existing line from Seward or Resurrection bay, passing through the Matanuska coalfields on to Fairbanks and its destination, wherever that may be. Evidently such a road would be enormously costly, but it would undoubtedly give an immense impulse to the country's development.

Speaking of the extension by the Government of the existing railway from Seward to the interior, Mr. Fisher says:

I believe this road should be continued on to the coalfields and beyond them to the interior, and that if private interests do not care to undertake the task the Government itself should do so. The situation here is not like that in the Copper River country. No large financial interests are back of the railroad; no large investments have been made which it will be necessary for private interests to protect. Such a railroad as I have suggested will pass through a country which appears to have large agricultural possibilities as well as great mineral resources. These possibilities and resources, however, will require time for their development. The adoption of a leasing policy will take away from the promoters of such a road the lure of great gain from the exploitation of the coalfields. This exploitation clearly should be prevented in the public interest. But at the same time the Government must recognize that if it withdraws from private capital this incentive for railroad construction, the Government itself must assume the obligation of making possible that kind of development upon which it insists for the general good. It has been urged that the Government should meet this objection by guaranteeing the payment of bonds or the interest on bonds equal to the cost of the construction of the road. I can see no advantage whatever in this policy. If the Government is to guarantee the cost of construction, I see no reason why the Government should not own the road outright, whether it operates it or leases to an operating company.

Referring, however, to Government ownership of coal mines, he does not take quite the same view as the Mining and Metallurgical Society, for he says:

Unlike the Government ownership of railroads, public coal mining has never been held by the courts to be a function of Government. It would be regarded by many

²*Mining and Scientific Press*, November 25, 1911.

³Horace J. Stevens, *Mining and Scientific Press*, November 4, 1911, p. 585.

sincere and disinterested citizens as an invasion of the field of private enterprise, and would involve such general and uncompromising opposition that even those who believe in its adoption as a matter of principle should not insist upon tying up the coalfields of Alaska until the great economic and political questions that are involved in its exclusive application to these fields have been fought out to a practical conclusion. The true function of government is not merely the preservation of public order or the regulation of the conduct of individuals, but the carrying on of any enterprise which will promote the welfare of the community as a whole more effectively if carried on by the organized community than if left to the voluntary action of individual members of the community. But to determine whether a particular activity answers this test depends in every instance on a final and complete analysis involving a consideration not only of immediate results, but of the far-reaching consequences upon humanity and upon the social order. While, therefore, much can be said in favor of permitting the Government to enter experimentally into those fields upon which industrial development and the welfare of society depend, which perhaps may in the future include the development and distribution of power and the means by which power may be created, I do not believe that the Government alone should preempt those fields or exclusively assume their development until it becomes far clearer than it is today that their development by private enterprise cannot be effectively controlled. For this reason I am opposed to the policy of having the Government alone own and mine Alaskan coal.

The views of the Mining and Metallurgical Society on this phase of the subject are fairly set forth in Section 2 of the above recommendations. The contention here is that the Government should control the best coal in the Matanuska and Bering River fields in the interest of national defense. Having drawn this clause myself, I have naturally followed with interest the discussion of it which took place in committee and council meetings. The impression I received as a consequence of the debate was that the majority of the members do not think the Government, under the circumstances, will be assuming too much in opening these coalfields in this way. The inference being, in my own mind, as it appeared to be in that of other members, that the Government could and would be justified in selling such proportion of the high-grade coal produced at its collieries as exceeded the demands of the Navy. In this way the development of these coalfields will be assured and pressing local needs provided; at the same time these collieries would be opened in a proper manner, provided with the best equipment, and become an object-lesson to future operators in the territory.

If the mineral laws in the United States need revision, and it is pretty generally admitted they do, Alaska is a good place in which to begin. The number of existing rights already established there under the present laws is relatively small, but whenever it can be shown they have been honestly and legally acquired they should unquestionably be confirmed. If owners will agree to revision—such, for example as an abolition of the extralateral right—all the better for them and everyone else, except possibly the lawyers. After an effectual scheme for the revision of the mineral laws is worked out and successfully applied to Alaska, I believe the results will be so satisfactory that a general revision for the whole country will be demanded. It is certainly true, as George Otis Smith, the director of the U. S. Geological Survey, pointed out in his address before the San Francisco section of the Mining and Metallurgical Society on October 16, 1911, that "at the present time we are developing oil land with a law that was made, not exactly to help gold mining, but apparently to control and keep gold mining from going ahead too fast. It did not promote gold mining, and it is the worst kind of a law for oil development. Our general mineral-land law antedates the present knowledge of either geology or the technology of the industry and is completely out of date."

When, in the history of the country, was there better opportunity for this revision than now? The U. S. Geological Survey, the Bureau of Mines, the Mining Congress, and the Mining and Metallurgical Society are all interested and willing to advise upon, and even initiate, reforms affecting the welfare of the mining industry.

Mining in China, 1911

By THOMAS T. READ

Full details in regard to the mineral production and resources of China were given in the *Mining and Scientific Press* for October 7 and November 11, 1911, and it is unnecessary to do more than add a few notes upon matters of more recent occurrence. Of these, easily the most important is the abrogation of the concession of the Syndicat du Yunnan, Ltd., an Anglo-French company which held the mining rights over an area of 40,000 sq. mi. in Yunnan. In addition to its mining rights, the company possessed a concession for railroad building, but in the present temper of the Chinese people the exercise of this right was not within the bounds of possibility, and the company has wisely agreed to surrender its concession for a consideration of 1,500,000 taels (approximately \$1,000,000) payable in half-yearly installments of 250,000 taels each. The company was organized in 1899 with a capital of £35,000, and held a 60-year concession (renewable for 25 years more), but has been unable to accomplish much, on account of popular opposition in Yunnan. Most of the foreign mining concessions in China (with the notable exceptions of the Chinese Engineering & Mining Co., the Schantung Bergbau Gesellschaft, and the Peking Syndicate) have now been canceled, and there is little probability that any new ones will be granted.

A recent report from Tai-yuen-fu is to the effect that commercial quantities of petroleum have been found in the neighborhood and that a company of local merchants will be organized to develop it. If the report is true, it greatly extends the area in which petroleum is known to occur in western China. It begins to seem probable that the general area between 30° and 40° N. lat. and 102° and 112° E. long. may eventually develop into a petroleum-producing territory of some importance.

Statistics from China are always a year old, at least. The Han-Yeh-Ping Iron & Coal Co., which operates iron mines at Ta-yeh, in Hupei, collieries and coking plant at Ping-hsiang, in Kiangsi, and blast-furnaces, steel plant, and rolling mills at Hanyang, near Hankow, reports that during 1910 it produced 130,000 tons of pig iron, of which 29,000 tons was sold in Japan and 15,000 tons in the United States; presumably nearly all of the remainder was converted into steel at the plant. The colliery produced 160,000 tons of coke and a total of 610,000 tons of coal during the year. In addition, an unreported amount of iron ore, probably about 100,000 tons, was exported to Japan, and a smaller amount to the Pacific Coast of the United States. It is not probable that the works at Hanyang have been much injured during the revolution, and they will probably be able to resume work soon after conditions again become quiet.

The Schantung Bergbau Gesellschaft reports that during 1910-11 it produced 237,544 tons of coal at Hung-shan, and 194,897 tons at the Fangtse mine. The operating profit was 247,719 marks which, by the payment of interest and amortization charges, is converted into a loss of nearly 600,000 marks. The Chinese Engineering & Mining Co., on the other hand, is a very profitable enterprise, having produced 1,117,312 tons of coal in 1910, at a profit of approximately \$1 per ton. The neighboring Lanchow mines, however, which were organized under Government auspices about two years ago, and which have been equipped to produce 4000 to 5000 tons per day, are only producing about 1200 tons per day and seem unable to operate at a profit.

Mining in China will be greatly interrupted by the revolutionary outbreak, and normal production can scarcely be resumed for some time. At the time of writing, the outlook is gloomy, and a speedy restoration of quiet seems quite unlikely. The famine in central China threatens to become more serious during the coming winter than during the past one, and combined with the long interruption of trade in the interior, will tend to produce a year of marked depression in 1912.

Mines of the Southern Sierras of California and Nevada

By MARK B. KERR

The eastern escarpment of the Sierra Nevada range, between California and Nevada, marks a tremendous fault culminating particularly in the great drop into the Mono Lake basin. A line drawn in a general northwest course projected through the centre of lakes Tahoe and Mono, would strike through the Sierras and touch most of the gold-quartz mines that have been heretofore prospected along this great mountain mass; but in the northern counties of Placer, Nevada, Sierra, and Plumas, the bold quartz outcrops are situated generally on the western side of the range, while in the southern counties of Alpine, Mono, and Inyo the quartz veins are in the heart of the uplift or near the eastern escarpment. The veins of the Plumas-Eureka district, at Allegheny in Sierra, and in the Washington district in Nevada county have been extensively explored and have been repeatedly described; but the

The valleys of this region range in elevation from 6000 to 8000 ft. above sea-level, and the snowfall begins early and soon blocks the roads. The season is short, and all winter supplies, of any bulk whatever, must be hauled in and the plant made snug and protected to withstand these heavy storms. This renders prospecting and mining expensive and difficult. The ranges east of Mono lake all have the same approximate strike parallel to the crest of the Sierras, and form, in reality, a portion of the structure of the Great Basin plateau. The quartz outcrops are bold, and the veins mark great dynamic disturbance, the ore deposits generally being along fracture planes or fault fissures. While in some places these veins are not in granite, but along contacts of either porphyry or slate with granite, the same general structure exists, and signs of great volcanic activity are much in evidence. Toward the east

SCENERY IN THE HIGH SIERRAS.

OUTCROP OF THE MAMMOTH LODE.

more southerly counties are still comparatively unexplored and inaccessible.

A State wagon-road from the Yosemite by way of Hetch Hetchy and the Tioga mining district has just been finished after years of delay, but packhorses must still be used over the steep trails by those desirous of prospecting or camping out in this region. In winter the heavy snows accumulate and avalanches frequently rush down the steep eastern escarpment. At Lundy, a little mining village near Mono lake, such an avalanche last year not only destroyed this village, but completely demolished the neighboring power-plant, and all were killed except the wife of the superintendent. The good people of Bodie, after a gallant fight in the storm, came over the mountains some twenty miles on sledge, and brought out the only survivor, who was dazed and not informed of her husband's death for months afterward.

Mono lake, a body of water about fifteen miles wide, is situated in a large sink about 6500 ft. above sea-level. Its shores are covered with sand and pumice, but irrigation does wonders, and many green spots, with horses and cattle grazing, stand out as oases in the otherwise general desolation and loneliness. The lake was formerly fresh and of much greater extent, the outlet at one time being through a low gap toward Hawthorne, Nevada, but the waters now contain a strong solution of carbonate and sulphate of soda with chloride of sodium. Two islands have formed near the centre of the lake, and at the southeast corner of the largest one, which extends two miles from north to south, steam issues from a series of crevices which can be seen extending some distance into the lake. This steam cools when exposed to the air and is precipitated on the island in springs of good fresh water.

is the Excelsior mountain mass, ranging from 6000 to 8000 ft. in height. Along the summits toward Mina, veins of silver-lead are found.

Numerous large sinks with steep sides, generally of basaltic cliffs, are found irregularly over this region, such as Adobe meadows, Huntoon and Whiskey valleys. These are now dry and have no outlet. Gold is found at many points, and still farther eastward are desert valleys between isolated mountain ranges. Until the mines of Tonopah and Goldfield were discovered these were as little known as the deserts of Gobi or Takla Makan. The bottoms of these valleys are occupied mostly by borax and salt marshes, sometimes fifteen or twenty miles wide, without a shred of grass and only an occasional bunch of sagebrush, but yet patience and hard work can utilize these salts and make them of commercial value.

The extended view is the great fascination of these deserts, the outlook being only limited by the surrounding high ranges. The outcrops are so well defined that it requires little imagination to project the different veins to some intersection in depth, and greater chances may be taken in suggesting possible orebodies in a country like this where the direction of the veins is so easily traced by the outcrop, than is permissible in a wooded country where little of the surface is exposed. For the pioneers who penetrate these deserts, suffering from heat and thirst in the hot summers and exposed to the winter blizzards, only admiration can be expressed, for in many cases prospecting and hard work reveal that the grade of the ore is too low to pay. The output of such camps as Tonopah and Goldfield, where over a million a month each in gold and silver is regularly produced, however, lures the miner and promoter on to further efforts. The light-colored limestones

and porphyries, the black shales and basalts, combined with the different colored sulphide ores, all more or less eroded, give rise to fantastic shapes, where such names as Aurora, Castellated Buttes, Casa Diablo, Mammoth, Minarets, and Deadmans creek graphically describe the effect of such scenes upon the pioneer.

In the southern high Sierras the gold mines yielded their greatest output between 1871 and 1884, when the Bodie mines alone gave yearly more than \$2,000,000. The mines at Benton, prior to the activity at Bodie, yielded a gross output of \$4,000,000. The Tioga lodes, at the head of Leevining creek, are large and can be traced for long distances, but since the Great Sierra company, in 1889, built the expensive wagon-road, over 50 miles long, from Crocker by way of lake Tenaya, little has been done. The ore carries considerable silver. The May Lundy mine is credited with a yield of \$2,000,000 and is now under bond to the Tonopah Mining Co. The Standard mine of Bodie built the first long line for transmitting electricity.

Cheap power is what is needed in these mines, for until very recently, steam from wood furnished by the Mono Lake Lumber Co. was almost universally used. This lumber company has a good tract of timber land and can furnish timbers for any extensive development in this region, at reasonable prices. The Pacific Power Co., at Jordan, just below Lundy, has recently put in a large electric plant and is supplying electric power to Bodie, Aurora, Fairview, and Wonder.

By far the most picturesque of any of these camps is at Mammoth, in the Lake mining district, and near the border of Mono and Inyo counties. The outcrop of the Mammoth lode is large. The vein lies between quartzite and porphyry and is heavily stained by iron oxides. Specimens of free gold ore were taken out in 1879 and 1880, causing great excitement. The lowest adit taps the Mammoth lode 600 ft. under the outcrop, and in the past two years while the mill was running, the mine is credited with an output of \$200,000. Numerous streams and waterfalls fed by the melting snows rush down the mountain slopes, any one of which, on being harnessed, is capable of generating power cheap enough to warrant further development in this and many other properties now abandoned.

This country is now included within the Mono National Forest, and restrictions as to prospecting and securing rights of way and the necessary timbers for mining are bad enough as it is, without further tinkering with the present laws governing mineral location. If the leasing system of mining claims by the Government should be introduced into the United States, then the Government, in my opinion, should also build power-plants and deliver water, power, and timbers at reasonable rates, for it is hardly possible that any private company would care to organize and develop a power scheme under a Government lease, as is now suggested by certain officials of the Interior Department. The lack of steady development on mineral locations is the greatest objection made to present regulations, but if the small prospecting company were encouraged by giving it cheaper power, water, and mining timbers, then in my judgment more claims would be worked steadily. One good paying mine gives steady employment to many miners and quickly builds up a community, and the small prospector, in every case, is entitled to the credit of opening up the ground sufficiently to encourage capital to venture further. Any amendment to present laws should be designed to encourage more vigorous and steady work in these wild and almost unexplored regions, and to the discovery first of the mineral to be conserved.

From the foregoing it will be seen that these southern Sierra mines of Mono and Inyo counties have yielded to date approximately about \$30,000,000, and with the advent of cheap and effective power and better transportation facilities, such as are now available with the mines in the northern counties, renewed activity may be expected. To the sportsman, as well as the miner, the hunting and fishing will prove attractive, and I know of no place in California more interesting than this region in which to enjoy a summer holiday.

Literature of Ore Deposits in 1911

By WALTER HARVEY WEED

The publications on ore deposits issued in 1911 include a number of works of vital interest to the mining engineer, particularly to those engaged in valuing mines or developing prospects. This neither implies any great epoch-marking work nor a discovery of new laws of occurrence of ores, for the science is as yet in its infancy. Engineers examining a property still rely upon comparison with other developed deposits as a basis for judgment, but the applications of the searching methods of modern petrography in the study of polished surfaces and thin sections of ores and of wall rocks, of the newer chemistry, and of a recognition of the true meaning of physical factors, are rapidly developing this into a science in which the apparent vagaries of ore deposition are seen to have definite and recognizable causes. The present is yet a transition period in which the literature is still largely descriptive, with a few general papers dealing with principles, or giving generalizations to be tested by the experience of engineers in the field. The bold generalizations of Horace V. Winchell¹ a year ago, have been discussed throughout the year by many engineers. Mr. Winchell contrasts the process of superficial alteration and secondary enrichment in Arctic and temperate regions to the distinct disadvantage of the former, maintaining that in boreal climates there is less migration of material by solution, and secondary ores if formed were planed off by glaciation. His observations upon a veneer of secondary sulphides formed yearly are especially worthy of consideration by examining engineers, and I have personally observed similar crusts in British Columbia. His conclusions are, if sustained by experience, the most important announcement of recent years to the investing public. They may be summarized as follows: (1) boreal regions seldom contain rich and extensive deposits of secondary ore; (2) surface appearances are deceptive, and high-grade ores show a sudden decrease in value at a limited depth; (3) primary ores are likely to extend downward. In temperate zones, (1) deep-seated alteration is an indication of good ore below; (2) ore deposits in general are more abundant in warm and temperate climates; (3) they are not so likely to terminate suddenly or change rapidly in depth. Mr. Winchell's critics have cited exceptions, but do not appear to have contravened his sweeping generalizations.

The 'Characteristic Features of Replacement Deposits and the Criteria for their Recognition',² is perhaps the most important single paper of the year; it certainly is so to the average mining engineer. Replacement deposits have long been recognized as erratic and difficult of estimation of value. Mr. Irving's experience has given him a wide familiarity with the type, and his paper is therefore valuable for its accurate presentation of facts as well as the conclusions drawn. He shows that the shape of a replacement ore mass is due to: (1) relation to channel of ore-bearing solutions; (2) variations in chemical character and structural arrangement of enclosing rock; (3) manner in which mineralizing waters have affected the rock; (4) amount of material supplied in solution. The illustrations in the paper are excellent and tell the story peculiarly well.

The agency of manganese in superficial alteration and secondary enrichment of gold deposits described by W. H. Emmons last year has inspired a paper on the origin of silver bonanzas in the arid regions by C. R. Keyes.³ Mr. Keyes ascribes these valuable but most astonishingly erratic deposits to solution of the metals by salts in meteoric waters, particularly sodium chloride, with precipitation by the alkaline silicates of clay selvages of faults, shear and joint planes, etc. The latter process is a legitimate deduction

¹'Prospecting in the North,' *Mining Magazine*, Dec. 1910.

³Bull. Amer. Inst. Min. Eng., July 1911.

from the experiments made by Mr. Sullivan at the suggestion of myself, in the laboratory of the U. S. Geological Survey, and the extensive investigations on clays and soil constituents in the bureaus of the Agricultural Department, especially those of Milton Whitney on soil and those on road materials. This paper should be read by all mining men interested in the ore deposits of arid regions, but it is lacking in direct facts, and the references given to the work of others often prove illusive when consulted, so that the paper is speculative and suggestive rather than the presentation of proved theory. The genesis of mineralized sandstones, whose widespread occurrence in the United States, both east and west, as well as in Russia, Mexico, and South America, has led to many unsuccessful attempts to recover their metallic contents, is discussed by W. Lindgren. According to him, chalcocite, bornite, and chalcopyrite are primary ores and, with accessory galena and vanadium, are typical of the deposits throughout the world. They are described as epigenetic and not of true sedimentary deposition.

In the field of descriptive works there is a wide variety. The State geological surveys of Australia contribute several papers describing the ore deposits of that island continent which suggest comparisons with Arizona and Mexico. The Queensland and Western Australia geological surveys publish bulletins which are not as widely read by mining men as they should be, since they are not readily accessible, and their important deductions are too frequently concealed in a mass of local description. Our own geological survey has contributed several volumes of permanent value, besides carrying out its recent policy of publishing reconnaissance notes on newly discovered mining districts. The monograph on the gold placer gravels of California, by Mr. Lindgren,⁴ is the result of twenty years of observation and study of these deposits by himself and other members of the Survey. It is a noteworthy contribution to the subject by our foremost living mining geologist. Cobalt's silver deposits are discussed by R. Hore, who gives a careful and concise description of the rocks of the district,⁵ but only brief and rather unsatisfactory notes about its ores or their occurrence. To the engineer the account by W. G. Miller⁶ is full of interest, showing by maps and cross-sections the relations of diabase, Huronian, and Keewatin. He considers the magmatic vapors from diabase the source of the ores, but that surface waters working downward played an important part. He finds, however, that secondary enrichment is less important than other geologists believe.

The Huelva copper deposits of Spain have been controversial ground for geologists for many decades. Two new papers have appeared in 1911. Collins⁷ has given a pithy, description in which he notes a popular error that the great lenses of cupriferous pyrite are uniform in composition. He has also justly called attention to the complex lead-zinc-copper ores of several of the lenses. Attention is also called to the surface, or chalcocite enrichment, and another 'deep' secondary enrichment of pyrite by chalcopyrite as myriads of irregular interlacing strings from $\frac{1}{500}$ in. up to an inch thick. This he ascribes to crushing and fissuring of the pyritic masses followed by enrichment. The association of chalcopyrite with calcite, dolomite, and quartz is noted, and the genesis ascribed to the intrusion of later basic dikes, the deep enrichment coming from the original copper-forming source whose ascending solutions now highly alkaline, deposited mixed sulphides and but little pyrite. A second paper,⁸ by a Spanish geologist and engineer, discusses the specular iron deposits of Huelva and their relations to the copper deposits. His theory assumes one source for the copper and complex sulphides. The sulphurous emanations at or near eruptive centres formed cupriferous pyrite deposits in crushed zones in schist which

were enriched by hydroxidation in the middle portion. Sulphides dissolved in acid waters formed replacement enrichment and another portion dissolved by alkalies traveled far from eruptive centres and formed banded complex sulphide deposits.

The geology of the Breckenridge district by F. L. Ransome⁹ is a well written account of one of Colorado's lesser but productive and interesting mining districts. The illustrations are pertinent and the facts well presented, though the book is rather large and its subject-matter too varied to hold the average reader who is not personally interested in the district. An excellent example of geological observations of general interest obtained in the course of a mining engineer's professional examination work is given in a paper by F. J. Pope on the ore-shoots of Pachuca, Mexico. The splendid geological report on this district by Ezequiel Ordoñez, published by the *Instituto Geológico Mexico* some years ago, has given an idea of the magnitude of these veins, which contain what are probably the largest bonanzas of high-grade silver ores extant today. Mr. Pope's¹⁰ observations show an association of these bonanza ore-shoots with phases of the igneous rocks resulting from magmatic differentiation. Descriptions of geologically unknown mining camps appear in the current periodicals, that of Hostotipaquillo, Mexico, by S. J. Lewis¹¹ being especially timely in view of the prominence of that district in the past year. The gold deposits of the Philippines are described by H. G. Ferguson¹² in a paper giving his personal experience and observations at the more important mines. He gives a conservative but fairly favorable view of the future of the industry of the Islands. The Transvaal gold deposits are described in two interesting papers. The first, by A. L. Hall,¹³ on the Pilgrims Rest district, bears the imprint of 1910, but reached most readers in 1911. This paper deals with a district yielding about two million in gold a year and containing 14 interbedded 'reefs' mostly in dolomite rocks forming the middle of the Transvaal series. The ore is a dirty white honeycombed quartz carrying minute particles of gold yielding \$9 to \$13 per ton. The reefs are small, the most profitable being but 8 to 24 in. thick. The second paper, by W. E. Bleloeh,¹⁴ discusses the correlations and age of the banket deposits of the Rand. It is seldom that a theoretical discussion of this kind has such an immediate application to development work. The gold deposits of the Porcupine district, in Ontario, have been described in numerous papers in the *Canadian Mining Journal* and have been given much space in the technical press generally. The general geology of the district is relatively simple, but the gold occurrence, which is marvelously rich in patches in one or two mines and occurs in sparser quantity over several townships in many veins, appears to be governed by minor geologic features demanding close detailed study. The long-looked-for monograph on the geology and ore deposits of the Lake Superior region, by C. R. Van Hise,¹⁵ has at last appeared, and sustains the reputation of its author, whose views on the mining districts of this region are so well known. The book should be owned by every engineer interested in iron ores.

The Etheridge Prospecting Syndicate has applied for two 100-acre leases on the Finasleigh river, about 21½ miles west of Hot Springs, Queensland, Australia. As this is about fifteen miles in a northeasterly direction from Georgetown, some idea may be formed of the extent of this great mineral-bearing belt. As a proof that there is rich ore existing in the deep ground on this field, recently a solid mineral specimen was taken from the Durham Consols mine at the 750-ft. level. The mineral weighs a little over 7 lb., and coarse gold can be seen all over it.

Progress in Cyanidation of Gold and Silver Ores During 1911

By ALFRED JAMES

Introduction.—America still holds pride of place for advanced practice during the year, although the tendency has rather been to settle down and to assimilate the great advances of the past year or two. One is inclined to regard the Santa Gertrudis mill as absolutely the best example of a silver-gold mill on up-to-date lines. In every way this mill is noteworthy, whether for the trouble taken in the preliminary investigation, the competitive nature of the practical tests, the expert talent assembled from all quarters, or the great success of its working. On the other hand, Africa is coming forward prominently, and there are signs of the more general adoption of methods of great success elsewhere. In this review I last year¹ ventured to suggest that F. L. Bosqui, assisted and not hindered by local talent and experience, would probably give a good account of himself, and the new Brakpan plant, for the success of which W. L. Honnold gives Mr. Bosqui well deserved credit, has signalized itself among recent African plants in being successful from the outset. The Brakpan is notable also as being the first example on the Rand of a mill on modern Mexican lines; thus agitation instead of being by pump transfer is by Pachuca tanks, and the gold in solution is recovered by filtration instead of by decantation, and precipitation is by Merrill zinc-dust process instead of by zinc shaving. The first dividend paid in South Africa from a modern mill—Pachuca tanks, Dorr thickeners, and filtration—seems to be that of the Lonely Reef in Rhodesia, to which credit is due for having at work the first plant of this type in that territory or on the Rand. A feature of Rand practice is the apparent difficulty of estimating the value of the gold in slime, pulp, and cyanide solution. That the difficulty does exist is shown by the discussions on the subject at the meetings of the Chemical, Metallurgical & Mining Society of South Africa, and the official report on the Adair-Usher and Butters results at the Crown Mines. At the same time, it seems almost inconceivable that groups of such great responsibility could be misled. Only a year or so ago the Adair-Usher results (readers will probably remember the criticism of the secretary of the company on the remarks in this review) were reported to show a saving of 5d. per ton over the decantation process. The chief mining group was publicly reported, without denial on its part, to have paid a large sum of money for the right to use the process. It now appears from the Crown Mines official report that the Adair-Usher residue was really 0.423 dwt. instead of 0.225 dwt., the apparent value when samples were taken in the usual way. A fuller account of this interesting report is given under filtration.

In another way Africa has also been prominent. Earlier in the year there were glowing reports on what the Gieseke mill was to do for the industry. Surprise at this was all the greater because it was evident to anyone of experience in ball-mill practice that the mill could not be the success claimed, because it has long been shown that for economical grinding in a tube-mill the elimination of the already slimed material is essential. The Gieseke mill combined a ball-mill with a tube-mill as one unit, the whole of the product of the ball-mill going without separation into the tube-mill portion of the appliance. It was therefore manifestly uneconomical. In addition, it has been common experience from the time of the original Globe, Lamberton, and other ball-mills that the wear and tear of iron or steel balls, when wet-crushing, was enormous, and there was no reason to anticipate any less wear and tear with the Gieseke mill. Indeed, the Krupp mill is the only one which appears to be able to stand the wear and tear of wet-crushing with iron or steel balls, and even in this mill the wear and tear is very much heavier than when dry-crushing. Last year in this review I ventured to predict,

although the City Deep type of mill was then at the zenith of its fame, that a high proportion of the new South African mills would be designed for filtration instead of the hitherto impregnable decantation, and already this prediction seems to be completely fulfilled. It must be difficult to gauge the feelings of such pioneers as the Meyer & Charlton and New Goeh, which after putting in the filters which enabled them to show recoveries of 94%, relapsed to decantation—it has been stated for the sake of obtaining a mortar-box sample!

India, too, is attacking other methods for the treatment of slime, and the erection of an up-to-date plant is anticipated at the Champion Reef mine; details are not available, but it is understood that the plans provide for Pachuca tanks and vacuum-filtration (Butters type).

West Australia pursues its already evolved practice. Much metallurgical skill has been applied to discover a less unsuccessful system of treatment of the Gwalia Consolidated antimonial ore. On the other hand, H. T. Brett, late of West Australia (of Ivanhoe pan fine-grinding fame), seems to have no doubt as to the correct method of meeting successfully his similar problem at the Globe & Phoenix.

Cornwall, curiously enough, is evolving practice which may later become a potent factor in gold ore treatment. Arthur Richards, who has made no little success of fine grinding of local tin residues with a consequent production of tin only surpassed by the largest mine or mines in the county, has set himself to increase the fine-grinding standard from -200 mesh to -400 mesh, and is endeavoring to find some more suitable appliance than the tube-mill for this particular purpose. Again, Doleath has now an equipment of smooth running—giving almost the impression of velvet cushioned—pneumatic stamps which in American or African hands would probably easily beat the record for tonnage per head per diem. It is a matter for surprise that someone has not taken a battery of these and determined their output on, say, 3-mesh screening with quick drop and most suitable quantity of water, leaving the finer crushing to be accomplished in some secondary appliance such as the tube-mill.

Before proceeding further it is fitting to refer to the satisfactory (from the metallurgical point of view) termination of the East Rand fiasco. It started with a reported huge loss of gold in the cyanide plant altogether incredible to those knowing E. H. Johnson, the able chief metallurgist. As Mr. Johnson was referred to in this review last year as regaining the laurels for the Rand in the matter of crushing, the accusation or charge was all the more inconceivable to me, and it has given much relief and satisfaction to find that the official report of the committee not only entirely exonerates Mr. Johnson and states there has been no (such) loss of gold in the cyanide plant, but shows how the supposed loss has really been brought about as a result of overcalculation of ore content and tonnage by the mine officials. Mr. Johnson had my sympathy; I now add my congratulations.

New Mills.—Probably the most notable mills of the year are the Santa Gertrudis, Dome, Randfontein Central, City Deep, Brakpan, and Lonely Reef, the last a quite small mill but at the time of its starting probably the most up-to-date in Africa. The Lonely Reef company has already within three months after its starting the mill, declared a dividend. If the City Deep (decantation) be excepted as being really a last year's mill, possibly still somewhat in an unfinished stage, and the Randfontein Central as being of the standard but now obsolescent decantation practice with a vast number of stamps (600) instead of a greater proportion of tube-mills, it will be seen that all these new Mexican, Canadian, Rand, and Rhodesian mills have points in common. They all include stamps of 1250 lb.

¹Mining and Scientific Press, January 7, 1911, pp. 52-56.

or heavier, Dorr type thickeners (Brakpan excepted), air-lift agitation (Pachuca tanks), filtration of slime, and, with the exception of Lonely Reef, Merrill zinc-dust precipitation. They appear to have gone to work smoothly from the start (except the Dome, not yet started) and to be giving results which are records for their particular territories. The Stratton's Independence mill, treating dump, and the Alaska Treadwell mill, treating concentrate, are also noteworthy, as will be seen later. The Tonopah Belmont, Modder B, and Palmarejo mills are not included, as details of the starting of these mills are not yet at hand.

Of the Santa Gertrudis mill, it is proper to state that the extraction from the outset has exceeded the estimates, and that it amounts to over 90% of the silver. Exact figures will be given in a paper shortly to be published by Hugh Rose. The mill is of 600 tons capacity and is being brought up to 800 tons by a small additional expenditure. It includes 4 gyratory crushers; sixty 1550-lb. stamps; 14 Dorr classifiers; 6 primary 5 by 16-ft., and 4 secondary 5 by 20-ft. tube-mills; 5 primary 35-ft. and 3 secondary Dorr thickeners; and 18 Pachuca tanks. A feature of the mill scheme is primary and secondary treatment almost all the way through. Even the agitating in continuous agitators is not in one operation. The pulp, when a little more dilute than 1:1, is agitated in a battery of 8 Pachuca's, is then elevated by air-lift to a launder, whence after dilution with 4:1 of barren solution, it flows through a second set of Dorr thickeners for a second treatment in 10 Pachuca's. Filtration takes place in 4 Merrill presses, the water used for sluicing being recovered by two 35-ft. Dorr thickeners. After classification in 2 sand filters, the solutions are precipitated by 6 Merrill precipitation-presses in two circuits, one involving complete precipitation, the other and larger reducing the amount of bullion in solution in course of flow. The Merrill slime-press is officially reported to be doing everything expected and to be showing greater capacity than originally claimed and to recover a high percentage (98%) of gold and silver in solution at a cost of $2\frac{1}{2}$ to 3d. per ton. This takes no credit for the additional extraction obtained in the press, but actually debits the press with total dissolved metal—under 2 grams of silver—in the residues, although the two grams and more is undoubtedly extra extraction obtained in the press itself during the treatment with barren wash. The above cost does not include royalty or the loss, perhaps $1\frac{1}{2}$ d., in dissolved silver and gold. The zinc-dust consumption is stated to equal the weight of bullion recovered (1:1).

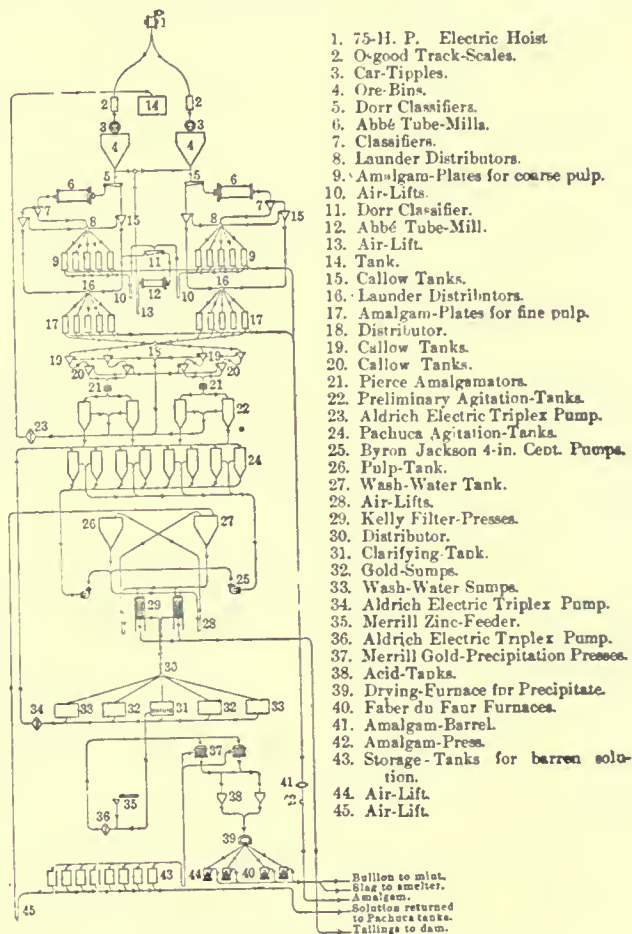

The La Blanca mill, which started at the close of last year, is reported to be obtaining an extraction of 92.8% silver and 95% gold, and to be milling 300 tons per diem at a cost of ₧4.40. The Moore filter is used in this mill and is stated to show dissolved silver to the value of 3 to 4 grams only on the residues from 750-gm. original heads.

Some mystery appears to hang on the Benoni mill. Last year the technical press gave full details of the proposed equipment, the chief new feature of which appeared to be the Way-Arbuckle slime-plant. It is reported that after many delays the mill was started in October to comply with certain Government regulations, but that the slime equipment is not yet in working order; doubtless full information will be available later, and it is to be hoped that Mr. Way has made as great a success of the Benoni mill as he previously made of his New Kleinfontein plant; but the latter was based on the treatment methods prevalent at the time, whereas the Benoni slime-plant would appear to be based on practice as yet unproved and untried; except in so far as the unsuccessful experiments at the East Rand may be held to apply to it.

The New Dome mill has had a setback owing to the disastrous forest fire which has necessitated reconstruction. From the published description it would appear to be a mill of standard modern type: forty 1250-lb. stamps, Dorr classifiers and thickeners, 4 tube-mills, continuous Pachuca agitation, Merrill slime-filtration, and zinc-dust precipitation.

The cyanide plant at Treadwell is notable as an example of a recent concentrate plant as well as for the extreme attention to detail characterizing the design. W. P. Lass gives a full description of it in the *Mining and Scientific Press* of October 21, 1911. Filtration takes place in Kelly presses and there is Merrill zinc-dust precipitation.

The Stratton's plant is left until last, as it is undoubtedly one of the most noteworthy achievements of the year. Readers will remember that the treatment cost of the West Australian telluride ores was brought down from a very high figure in the early days to as low as 11s. 6d. per ton.² It was a brave if not audacious proposal, therefore,

FLOW-SHEET, ALASKA TREADWELL MILL.

to spend a large sum on the erection of a mill to treat telluride dump rock of a grade of 3 dwt. and under! How Philip Argall has succeeded may be seen in the November number of *The Mining Magazine* and also in the account of the November general meeting of the company. He has justified and beaten his estimates, and congratulations are none the less sincere because he has accomplished what few would have dared venture. Briefly, Mr. Argall beneficiated the dump at a cost of \$1.40 per ton by crushing, concentration, and cyanidation of sand and slime, using gyratory crushers, rolls, Chilean mills, classifiers, concentrators, tube-mills and reconcentration, vacuum-filtration, and zinc-shaving precipitation. It should be noted that the concentrate (3%, containing 44% of total gold in ore) is not treated, but is sold to the smelters on advantageous terms, but the figures include bromo-cyaniding, whenever necessary, of the slime. During the fiscal year 109,800 tons containing 17,288.96 oz. of gold was treated, with a recovery of 7546.8 oz. in the concentrate and 4814.8 oz. from the sand and slime; a total recovery of 12,361.6 oz. or 17.5% for a profit of \$65,000.

New Processes.—It is the experience of many that old processes continually reappear under new names with some ingenious change ringing on old chemical or electrolytic methods. It is not, therefore, my practice in this review to refer to newly-proposed methods until the ordeal of

²Great Boulder Proprietary—see this review for 1906.

practical trial has strengthened rather than effaced them. Usually money and time and trouble may be saved by a knowledge of the result of scientific speculations in the past, and a compilation of these schemes is needed, even though it prove a record mainly of obituary notices. The memory of the old Cassel electro-chlorination process still lingers, and with it the knowledge of the troubles then met in finding anodes that would stand the disintegrating action of passage of current, electrolysis of solution, and wear and tear of agitation of ore-pulp at the same time. It was obvious that the cyanamide process as described by J. C. Claney must encounter just the difficulties that worried workers with the older process, and from all accounts this trouble has in fact caused delay in bringing the process to a working stage. In the same way the difficulty of the electrolysis of dilute solutions with complete precipitation of metals yet exists, and the troubles that befell Peletan-Clerici and Riecken still await the enthusiastic inventors who chronically rediscover these processes. Long before the advent of the Adair-Usher process it was found that displacement by upward solution was so imperfect as to be unreliable, and that the attempt to recover deposited thickened slime by a screw-conveyor working under water had caused the failure of many a filter or slime-treatment device, and it was, therefore, not a little surprising to learn of the huge sum (£30,000) stated to have been expended on the Arbuckle experiment at the East Rand. Similarly, the continuous reshuffling of the chemical reaction, solution, or oxidation processes led me to write for the last International Chemical Congress a brief sketch of the results of the employment of various oxides, alkalies, lead salts, lead coating, halogen salts, hypochlorites, accelerators, mercuric cyanide, and alkaline persulphates, with a note of their original introducers into the field of cyanidation. A glance back at history is often sufficient to indicate the part probably to be played by a 'new' method, and that, too, even when the method involves some ingenious application of nice chemical reactions. And as this was my excuse to the reviewer who criticized the omission from 'Cyanide Practice' of any reference to a certain process then advertised but never since heard of, so it may last year and today be taken as my reason for not including in this review of progress in *practice*, comments on ingenious scientific speculations.

Agitation.—The attempts to turn an air-lift agitator into a continuous decanting device have so far had as little success as the old attempt (this year repeated) to filter slime from the bottom of the agitation plant through a filter-bed immediately under the agitator. The feature of the year has undoubtedly been the almost universal adoption of the continuous system of agitation in Pachuca pioneered by A. Grothe, whose able and ingenious article on the principles of agitation in air-lift tanks has given us all food for much reflection. Who before was brave enough to discount what many thought the supreme advantage of the air-lift accelerated agitation, and to argue from the downward travel of the particles only? That article³ should be read by all. But none the less, the continuous agitation method has brought to light many snags and pitfalls hitherto unsuspected, and from plants on all sides valuable experience is at hand as to means of overcoming the difficulties that crop up. Probably the best course for the intending user is to get into touch with Mr. Grothe at once and to obtain from him the latest results; otherwise he may repeat the experience of a company whose mill is stated in the technical press to have suffered delays of some months on account of the non-working of a locally-devised adaptation of the Pachuca tank. It cannot be too strongly urged that anyone modifying a standard agitator should first experiment with a glass model; he would then find that much of the so-called agitation is merely the escape of bubbles which, cleaving through the volume of liquid, make a great show at the surface, but fail to even slightly modify the descent of all but the finest particles of the slime-pulp.

The originally proposed method of connecting the tanks by inclined pipes is expensive, the more so as by-pass pipes are necessary and the stoppers are awkward to get at, and valves get choked by sand. M. H. Kuryla air-lifts the pulp across any particular tank it is wished to cut out, and Mr. Grothe has central feed and discharge tanks with the Pachuca grouped around so that any of the tanks can be made No. 1, and thus any particular tank can be cut out without difficulty. All tanks have discharge valves, and thus any tank can readily be made the last of the series. A simple system of continuous agitation has also been described by Huntington Adams.⁴ This method can readily be adapted to existing tanks, and has the advantage of having all connections at the surface of the charge, but to one who has not seen the apparatus in operation the by-passes would appear liable to choke and the system of a variable-cut sampling box at each tank would seem to call for attention and adjustment—otherwise why the adjustments?—whereas it has been shown that the Grothe method does automatically give a pulp of equal screen analysis throughout. The provision, however, in the last tank for agitating a partly filled tank when this is used as a reservoir for filling filters is surely a step in the right direction.

The form of dropping spider shown in the description of the Treadwell plant⁵ is worthy of note. A spider which will start up within 15 minutes a densely-packed 30-ton mass of high specific gravity concentrate is an appliance of considerable value in the agitation of concentrate. The Trent tank has come into prominence during the year, mainly by reason of the description of it by J. W. Hutchinson.⁶ He describes it as the most serious competitor of the flat-bottom agitator and as a good means of bringing flat-bottomed tanks up to an efficiency comparable to that obtained by Pachuca. The agitator resembles a garden sprinkler, submerged in the pulp, which it agitates by reason of the motion imparted to the radial arms by an issuing stream of circulating pulp. In a personal letter Mr. Hutchinson states the Trent agitator takes 6½ hp. to operate in a charge of 200 dry tons at a dilution of 1½:1.

Amalgamation.—In parallel with the practice of concentration ascribed to F. L. Bosqui in this review of last year, whereby the tables immediately after the battery were omitted and concentration limited to vanners or slimmers after the tube-mills, several mills in South Africa do away with plates after the mortar-boxes and rely on after tube-mill amalgamation only. It has been foreseen that plates after the mortar-boxes would have to go, because the coarse-crushing now taking place in the mortar-boxes yields fragmentary pulp quite unsuitable for amalgamation on plates, but this removal of the battery plates in no way obviates the difficulty of the effect of cyanide solutions on amalgamated plates, and W. C. Caldecott avoids this by his scheme of dewatering and adding cyanide solution after the tube-mill tables. C. W. Merrill, similarly, at the Dome, is unable, by reason of his employment of amalgamating plates, to avail himself of any advantage arising from crushing in cyanide solution, and either dewater his slimed pulp prior to agitation or does not introduce cyanide solution until the pulp is in his press. The Caldecott system yields a beautifully separated and dry (10% moisture?) product adapted to his special requirement—the adding of cyanide solution with as little dilution as possible—but it is questionable whether a valveless table is the most satisfactory or economical method of accomplishing this object. A waste of vacuum at the scraper and a wear and tear of cloths seems inevitable, and possibly a continuous filter of the Askin Nicholas-Oliver type would be more satisfactory in the long run.

A recent advertisement shows that J. V. N. Dorr has fitted a vacuum-filter to the bottom of his well known classifier, presumably to give a dryer product. Mr. Argall,

³Bull. Amer. Inst. Min. Eng., August 1911.

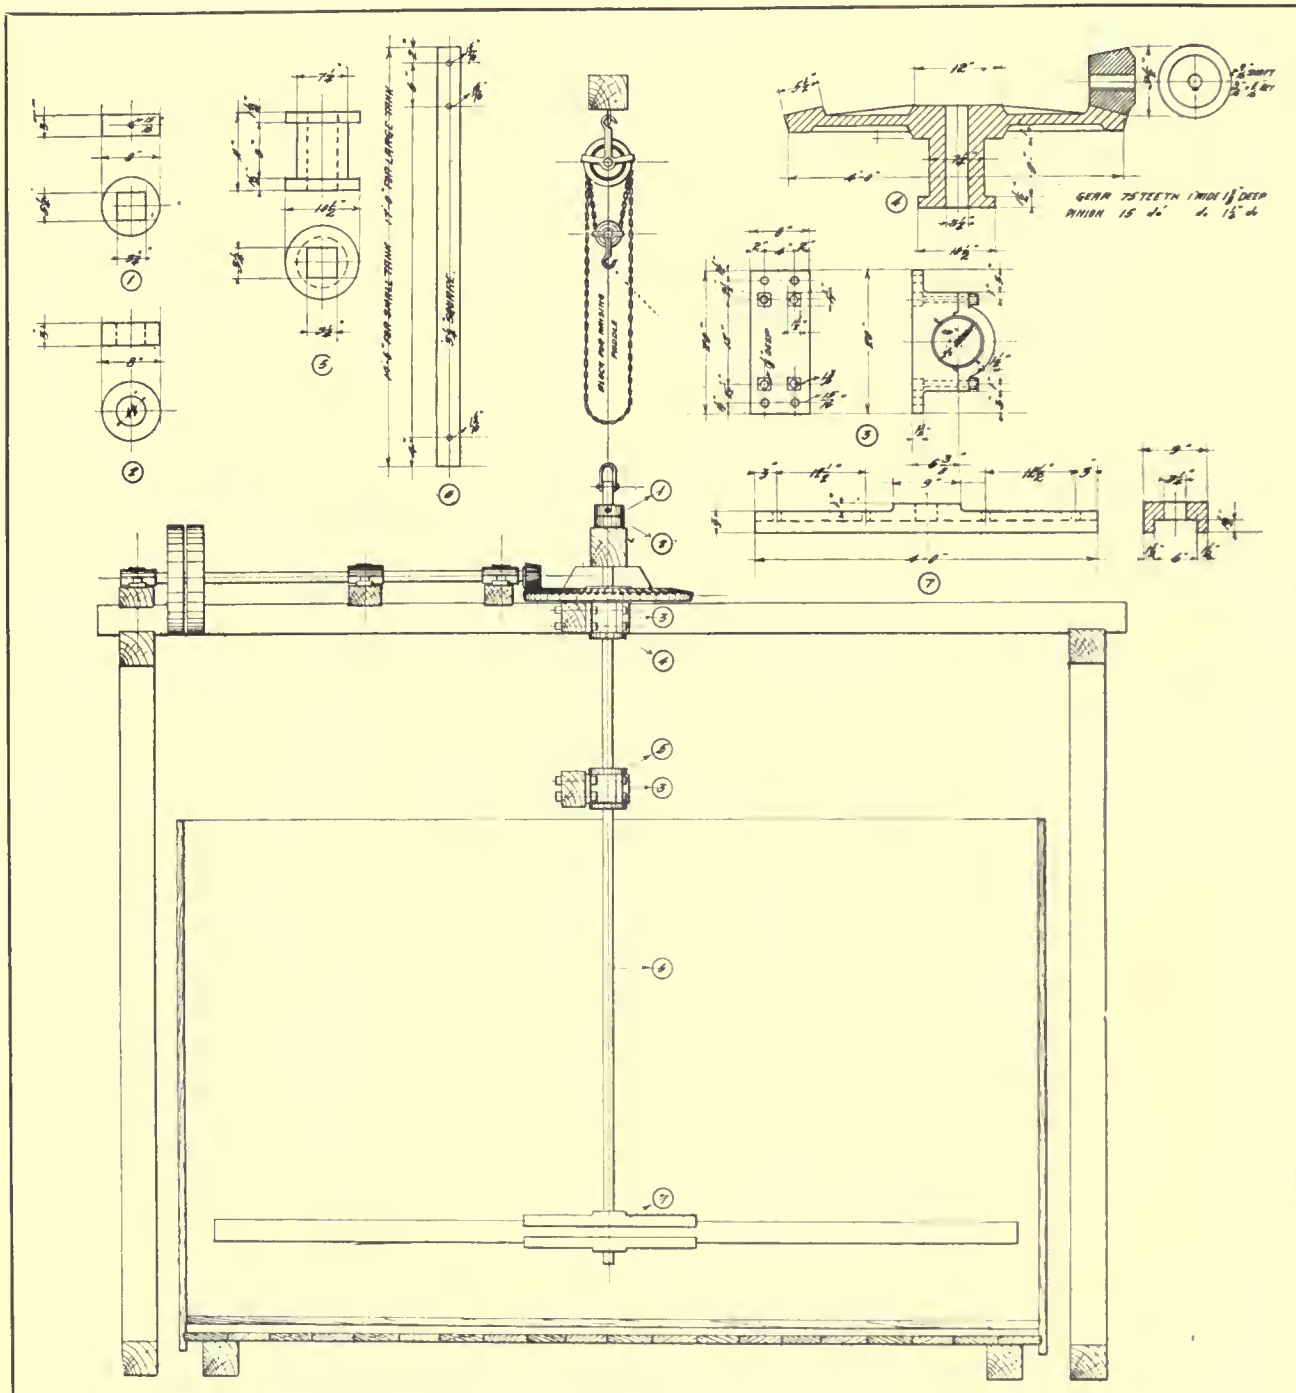

⁴Mining and Scientific Press, October 21, 1911.

⁵For description of Goldfield Consolidated Mill, see Mining and Scientific Press, May 6, 13, 20, and 27, June 10, 1911; also, Eng. & Min. Jour., June 17, 1911.

at Stratton's Independence, classifies and dewateres his pulp down to 15 to 20% moisture, treating 200 tons per day with $\frac{1}{2}$ hp. By means of two screen-conveyors he presses the sand and withdraws it with considerable control of fineness of particles and dryness.

For thickening slime-pulp the Dorr type thickener, and its last variant, the El Tigre, holds the field by reason of its simplicity, its low operation and maintenance cost, and

of a series of parallel corrugated sheets placed at an angle of, say, 45° to the surface and continuing for some distance (18 in.) below. The corrugations are stated to regulate the flow of descending slime and ascending clarified water without interfering with the settlement of the rest of the pulp. At the Sons of Gwalia an experimental plant is stated to have improved the thickness of the pulp from 26 to 41 per cent.

ADJUSTABLE AGITATOR IN GOLDFIELD CONSOLIDATED MILL.

its efficiency. For dewatering slime-pulp the Oliver type filter is probably as convenient as any other apparatus. The method of filtering (dewatering) slime by squeezing it in a folded belt between rollers, described in this review for 1909, is still being experimented with in Australia, and the latest development has been recently described in the *Journal of the Western Australian Chamber of Mines*. A considerable amount of work has recently taken place in South Africa and Australia on systems of dewatering slime by assisted settlement such as that included in the Way-Arbuckle Benoni plant, or that described so fully by Gardner in the May *Journal of the Western Australian Chamber of Mines*. This system depends on the acceleration produced in settlement resulting from the employment

Clarifying Solutions.—E. J. Sweetland, the Treadwell staff, and C. W. Merrill have all invented presses for clarifying solutions with flowing or sluicing off of the sediment. It is perhaps too early to predicate as to the success of these presses; this must to a considerable extent depend on the nature of the suspended matter in the solutions to be clarified. At the Santa Gertrudis recourse is had to sand filters; the well-known Delme (hand-cleaned) clarifier was specified for the Palmarejo mine, but at the last moment sand filters have been substituted here also.

Crushing.—The race of the Rand to heavier stamps has received a serious check, and the City Deep mill does not appear to be entirely satisfactory. Indeed, the Nissen stamp is reported to have shown up remarkably well against

this 'last word' in Rand mills. It may be assumed that for the present Rand practice will for the future assimilate itself more closely to the Mexican and New Zealand practice of increased ratio of tube-mill to stamp. Unfortunately, no figures of performance are available. It was known that the overloaded and over-revolved Rand tube-mills almost immediately after their original installation, passed the margin whereby crushing capacity at the then standard of fineness could be more economically increased by addition of tube-mills rather than of stamps, but on the other hand, the increased fineness resulting from tube-mill grinding has brought about increased extraction and sent up the Rand standard of fineness from 60 mesh to 90 mesh. Indeed, the greatest opponent of tube-mills on the Rand is apparently at last convinced and has not only laid down a record ratio of tube-mills to stamps for the Rand at the Benoni, but it looks as if the New Kleinfontein plant itself was following suit on the same lines. We may thus take it that, in spite of the greater horse-power used in grinding through tube-mills, the practice is one that pays.

In this review reference has been previously made to

HEAVY STAMPS AT CITY DEEP.

the low ratio, 2 to 4% of tube-mills to stamps prevailing on the Rand as against 16.6 and even 20% elsewhere. An instructive table is given in the *South African Mining Journal* for September 2. It shows that the mills with a tube-mill to stamp ratio of about 1:18.5 crush from 11 to 20 tons per head per diem; when the ratio is 1:20 the output is from 10 to 13 tons per diem, with a ratio of 1:25 the output descends to from 9 to 10½ tons per diem, and those with only 1 tube-mill to 30 or more stamps show only 8 to 9½ tons per diem; but the value of the table is diminished by absence of any note of the weight of the stamps or of the total horse-power employed.

The trial of the Nissen stamp at the City Deep has provided some extraordinary results; it would scarcely be too much to ascribe a superiority of over 30% in crushing capacity, weight for weight, for less horse-power and repairs, and that, too, taking a considerably coarser feed. It is evident from the above results that a limit will be put to the development of heavy stamps in batteries of 5 heads per mortar-box, as the heavier the head the greater should be the area of shoe and die. A noteworthy point is made by J. W. Hutchinson,* who states that instead of increasing the Goldfield Consolidated mill by 40 stamps and 3 tube-mills as originally proposed, they obtained the desired output by the addition of 6 Chilean mills only between the existing stamps and tubes. Battery screens of 4 mesh were substituted for the existing 12 mesh with a resulting duty of 8½ tons per head. This scheme saved a month's time, \$100,000 in money, and yet increased the capacity of the plant by 40 per cent.

Fine Grinding.—E. J. Ball, in a paper before the Institution of Mining and Metallurgy, shows that present African

practice is to grind 130 tons of product passing 90-mesh screen for 75 to 90 hp. with a pebble load of 8 to 14 tons, depending on the wear of the liner. This gives a factor for comparison with the data of El Oro, Waihi, and other fields previously given in these reviews. A standard mill in South Africa consumes 7 hp. per ton of pebbles and produces 10 tons of ground sand per ton of pebble charge per diem, or, roughly, 1½ tons per horse-power through 90 mesh. El Oro produces 1.2 tons per horse-power through 200 mesh. Waihi figures are greater than these, but include the slime ore from the mill. The best feed appears to be 30 tons per ton of pebble load at a moisture of 38.8% (Walter Neal). The pebble load is shown by Mr. Ball to be the best when the mill is filled to just below the centre of rotation, while the speed of rotation should be 10% greater than that given by Davidsen's formula. Now Ball's tests were so successful that he brought the efficiency of a makeshift tube-mill—an old chlorination barrel—from 3.87 (S.S) to 8.82 (V) and gave results comparable with those from present-day specially-designed mills. It is to be hoped ere long similar tests may be made on the economical limits of coarseness of feed and of irregularity of mine rock (substituted for pebbles).

There is but little fresh to chronicle in tube-mill practice. As previously suggested, Walter Neal's reverse screw outlet is becoming more and more widely used, and bar liners are displacing all other forms. The ideal liner would seem to be an El Oro liner with replaceable ribs or bars, so that the backing need not be wasted when relining is necessary. Richards (Cornwall) points out the necessity of having small pebbles as well as large in the charge of tube-mills newly started. After continued running, the necessary proportion of small pebbles is mechanically produced, but at the outset he finds output poor unless the charge is made up as stated above. Allen's point of rounding off mine rock prior to its introduction into the mill appears well taken, and is supported by the work of Davidsen and the experience of Neal. The original ten machines at the Great Boulder have treated a million tons of slime to date—a pretty good record. The latest type of machine, however, has adjustable periods of revolution enabling the cycle to be altered at will or even with the age (and lessening filtering capacity) of the cloths. It works automatically, the adjustment being by water-balance, with feed varied at desire, and is showing a good capacity even with the difficult St. George kaolin. On Great Boulder pulp this latest Ridgway type handles daily over 250 tons per unit.

Filtration. The fact that all the new great mills of the world referred to under 'New Mills' treat their slime by filtration, evidences how absolutely this method has displaced decantation. From West Scotland Street to Karangahake, from Karangahake to Kalgoorlie, from Kalgoorlie to the uttermost parts of the earth, filtration has progressed on its triumphant march; except for the Rand, where the New Consolidated Langhagte mill is reported to be designed for decantation, it may be regarded as universal. It is noteworthy that all the typical new mill plants noted, except the Brakpan, have pressure-filters in spite of the great advances made in vacuum-filters, mainly on the lines indicated by Crush in 1909, namely, the adoption of gravity-filled huge pipe-line plants emptying or filling in three minutes and thus avoiding or lessening cracks, in place of the centrifugal-pump-throttled slow-filling systems described in the technical press of that date.

Pressure-Filters.—The Dehne still easily ranks first for number of installations, and is the press adopted by such new mills of the year as the Lonely Reef and the Matabele Queen. The Merrill has given a remarkably good account of itself at the Santa Gertrudis, and the Kelly has been adopted for the treatment of concentrate at the Goldfield Consolidated and the Alaska Treadwell new mills.

Vacuum-Filters.—A spell of holy calm has supervened after the enthusiasm of past years. The Moore is reported to have been adopted for a further plant at Pachuca by an old friend there. The submerged filter has undoubtedly advanced since the adoption of the principle of rapid

**South African Min. Jour.*, Nov. 4, 1911.

**Mining and Scientific Press*, loc. cit.

emptying and filling. Charles Butters has been energetically moving in new territory, Africa and India, and the official report of the Crown Reef plant may be regarded as a veritable triumph. Years ago the Denny brothers pointed out the loss in dissolved gold in the decantation residues and their accompanying solution. It was reported that the total maximum further possible saving was only 8d. It seemed impossible to break down this stand and to save gold for people who thus plainly expressed their belief it was not there to save. Even the Ridgway demonstration which reduced decantation residues from 0.5 and 0.6 dwt. to 0.12 dwt. failed to shake this attitude, and when the same demonstration showed indubitably that gold was still being dissolved after the pulp had been agitated and treated by decantation, even then the possibility of this was locally denied. The official report on the working of the Butters plant at the Crown Reef should put an end to all this. The true average of Adair-Usher residue is shown to be 0.423 dwt. instead of the 0.225 dwt. stated. The Butters plant recovers the dissolved gold, and also by the use of barren solution wash further gold, to the extent of 0.332 dwt., 1s. 5d. per ton, and may under normal conditions be reasonably expected to show a gross saving over decantation of 0.20 dwt. (10d.), or a net saving of 0.12 (6d.) per ton of slime filtered with a treatment cost of 9d. per ton filtered. It may be reasonably anticipated that under normal conditions the Butters cost will not amount to anything like this figure. Under demonstration conditions extra cost will have naturally been incurred to bring the figure above normal. It will be remembered that the fixed submerged costs were given as from 6d. to 10d. per ton in this review for 1909, and with the huge-main gravity-filling system now being adopted at all plants, it may be expected that costs will be still further reduced.

The following cycle is given for comparison with the old ones published in 'Recent Cyanide Practice'. It well shows the advantage of the gravity-filling huge pipe-line plant to which an old pump-filling plant was converted, and is only possible, of course, by the use of the hydraulically operated valves first included in the rapid-filling Crush installations. By the use of 20-in. pipe-lines the cycle is completed in one hour, as follows, the time being stated in minutes: Fill, 3; form cake, 19; discharge pulp, 3; fill, wash, discharge with barren solution, 21; water-wash and cake discharge, 11; total, 57. This may be compared with a cycle of 2 hr. 5 min. by the old pump-throttling system. By the new method, not only a better washed product is obtained by avoiding the formation of cracks by long exposure of the uncovered cake, but also the unparalleled output of 7 dry metric tons per leaf per 24 hr. is achieved. The industry is indebted to C. W. Van Law, of Real del Monte, not only for the record established for the above work, but for much serious original investigation into the question of the continuous solubility of gold and silver in pulp after agitation, and even after filtration. Mr. Van Law establishes the necessity for dilution with barren solution after agitation, and for slight re-agitation to obtain best results. An extract from a letter dealing with one of the largest and most recent submerged-filter plants of the day gives point to the remarks above regarding the evils of throttling and the advantage of the Van Law cycle. "The bad feature of it is that the excessive time of change from slime to wash is worse than wasted, for it allows the cakes to crack. When giving a water-wash the time lost in manipulation, exclusive of discharging the cakes, is 36 minutes on each cycle. Allowing an hour and a half per cycle, that shows a 20% loss of capacity as compared with changing in 6 minutes."

J. W. Hutchinson's articles on the mill at Goldfield⁹ have already been the cause of the saving of many thousands of dollars by submerged-filter operators. He most carefully prevents unavoidable loss of the water-wash into which his cakes are discharged, pumps off all possible water to a storage tank, and uses it for diluting his Pachuea charges. Any enrichment of the solution is thus retained in the mill-flow for ultimate precipitation. His slime

residue flows to the dam as a very thick pulp, carrying little more than 33% moisture. Whether this method is an improvement on that of A. H. Smith, also at Goldfield, described in this review of 1909, is perhaps a moot point. Mr. Smith runs his residues into a pond with wash solution, settles, and decants, and to this extent may recover a larger proportion of value contained in the cake than Mr. Hutchinson, who decants from his tank; on the other hand, Mr. Hutchinson's method should be less costly and less liable to loss. But it would look as though he could make a higher recovery by following the example of Mr. Smith and decanting after the cake has been agitated with wash instead of after a dropping only.

The Ridgway has not been entirely resting on its laurels. From New South Wales comes the account of its having ousted a grouped-frame filter of well known type, and a plant has also gone into British Columbia. But in Africa its sponsors, having demonstrated its efficiency, have preferred to wait for a coming to terms by the mining groups rather than to undertake further expense for a problematical minute remuneration. The Thompson-Davis-Crush plants have this year introduced a further refinement by a contrivance which avoids the use of air (with its inconvenience of frothing) for agitation. Drage has brought out a filter in Australia which somewhat resembles a Ridgway set vertically. The Way-Arbuckle combination appears to have been long endeavoring to patent a somewhat similar appliance with double screen-area, judging from U. S. Patent Specifications issued June 6, 1911.

Heating Solution.—Year by year I refer to this in the hope that it may lead to a general communication of views as to the benefits or disadvantages of this course. The difficulty of precipitating gold from solution on the Rand in the winter months emphasizes the necessity for some such exchange of experience. The method suggested by Swen of reheating the air employed in air-lift agitators seems a simple and feasible plan of warming solutions and at the same time making less air necessary for a given duty. C. T. Rice¹⁰ refers to an increased recovery of 2% at the Desert mill resulting from heating the solution.

Precipitation.—The Merrill zinc-dust method has been gaining ground as a result of the careful technical supervision of the inventor and his associates. This method has been still further improved by the adoption of a two-circuit plan, the main circuit for reducing solution content during flow, and the secondary circuit for the complete precipitation of solution to be used as wash, etc. By the adoption of this system the consumption of zinc-dust has been reduced to 1:1 of bullion; indeed, even a lower consumption is claimed at some plants. The system has also shown to advantage in the precipitation of cupriferous solutions. The continuous feed of zinc-dust acting at once, instead of becoming more sluggish after a while, as with copper-coated zinc shaving, has given remarkably good results in dealing with such solutions, as witness the Goldfield Consolidated plant when the precipitate contains 43% copper. Undoubtedly, a drawback to the system is the large amount of oxide and impurities, perhaps 15%, added to the precipitate, all of which has to be fluxed off unless resort is made to acid treatment. Another drawback is undoubtedly the clogging up of the pipe system between the feed and the press with bullion precipitate—this latter difficulty should be easily overcome, and I am expecting Mr. Merrill to make his hold on the process greater than ever by supplying a specially prepared pure zinc-dust.

General.—Silver mills seem to have bulked more largely this year in the matter of advanced practice than gold mills; silver sulphide is not so easily attacked by cyanide solution as metallic gold, and this fact probably accounts for the advanced position in practice held by Mexico and for the extraordinarily high efficiency in gold recovery of the mills there. The keen enthusiastic emulation of the Santa Gertrudis, Real del Monte, San Raphael, La Blanca, El Oro, Esperanza, and Dos Estrellas mills reminds one of the similar position in Kalgoolie some years back, and cannot but make for great technical progress.

Iron Ore Movement on the Great Lakes in 1911

By GEORGE H. CUSHING

Approached from the standpoint of either one of the raw materials—iron ore or coke—the steel business in the North and East for the past year has been quiet. Ore shipments considered alone and showing a falling off of 10,000,000 tons, would very clearly measure the dullness in the steel trade, were it not for the fact that a great quantity of iron ore was held over in furnace stock piles and Lake docks from the season of 1910. To get a complete survey of the status of the steel trade, it is necessary to study the coke trade, and especially that of the Connellsville district, which still exercises a predominant influence over the blast-furnace business. The figures of coke production show an output of approximately 60% that of the preceding years, such as 1907. Lake iron-ore shipments, on the contrary, amounted to a little more than 75% of those of 1910, which were more than a million tons in excess of those of the big steel year of 1907. It being considered that coke consumption measures the extent of pig-iron manufacture and coke production, and this, for the last two years, not being in excess of 60% of the normal, it must be concluded that the furnace and dock companies have on hand both at the plants and at the Lake ports an enormous quantity of ore, or enough to keep them in operation, even though business should revive speedily, well along into next summer.

The Lake ore shipments, up to the close of navigation on November 30, 1911, totaled 32,130,411 tons. This compares with the record shipments by the Lakes of 42,620,201 tons in 1910, and shows a decrease from the maximum of 10,489,790. This was incidentally a decrease of 8,158,344 tons from the record made in the season of navigation of 1907. It marks, in fact, the smallest shipment, save one, of iron ore since 1904, which was the climax year of the 'rich man's panic,' started in 1903. In 1904, the Lake shipments amounted to 21,849,401 tons. The following year there was a gain of 12,000,000 tons, which took account of the revival of business following the 'rich man's panic.' There are some who believe that from the present outlook there is likely to be another such an increase in shipments in 1912 as a natural growth of business and reaction from the period of depression just now drawing to a close. A similar increase to that made in 1905 over 1904 is expected for 1912 over 1911. This would bring 1912 shipments up to the record total of 44,000,000 to 45,000,000 tons, and this has been and is being freely predicted. Mitigating against any such result, however, are both the accumulation on the Lake docks and furnace stock-piles as previously referred to.

The Lake shipments of iron ore, in fact, for the past four years have been lively, and this can only be accounted for on the basis that the iron trade has constantly been expecting a return of business prosperity which would warrant such enormous tonnages. That disappointment has followed consistently for the last three years is evident to every student of iron trade conditions, and the heavy movement of 1909 and 1910, taken with the shipments of this year, must leave a large accumulation in the hands of dock companies and users. Since no statistics are compiled showing ore on furnace stock-piles, this point can be made by conjecture only.

The shipments, as compiled by the *Iron Trade Review* for the past eight years, have been as follows:

Year.	Tons.
1904	21,849,401
1905	33,476,904
1906	37,513,595
1907	41,288,755
1908	25,127,091
1909	41,683,873
1910	42,620,201
1911	32,130,411

The statement of shipments by the various ports does not

give as clear an idea of the quality of ore used and the purpose to which it has been put as was the case last year. The principal shipping ports and the amount moved from each for the past two years are as follows, figures being, as usual, in long tons:

Port.	1910.	1911.
Escanaba	4,959,869	4,278,445
Marquette	3,248,929	2,209,380
Ashland	4,093,822	2,429,290
Superior	8,437,261	9,920,490
Duluth	13,609,155	6,934,260
Two Harbors	8,271,165	6,367,537
	42,620,201	32,130,411

While it is known that the metallic content of the ore shipments has been steadily decreasing for the past few years, an analytical review of the trade has not been made or published. At this time it is only possible to make the rough calculation which is naturally suggested by the amounts moved through the various ports. The 'bessemer old range' ores are commonly supposed to be shipped mainly from Escanaba and Marquette, while the lower grade ores, such as those from the Mesabi range, come from the other ports mentioned. According to these statements, Escanaba lost but little of its tonnage, its shipments being less than three quarters of a million tons below those of 1910, while Marquette showed a decrease of about a million tons. On the other hand, the business of Ashland was almost cut in two, Superior made a gain of a million and one-half, while Duluth, her sister port, lost almost 7,000,000 tons. Two Harbors, which is well up toward the head of the Lakes, and which ships about the same grade of ore as Duluth and Superior, lost approximately 2,000,000 tons. Making a rough estimate, it would seem that the low-grade ores bore more than 80% of the total loss in business, this making its own suggestion as to the relative manufacture of bessemer and of open-hearth steel.

In connection with the Lake shipments a point is brought out clearly by trade peculiarities this year. It is no longer possible to judge with any accuracy the iron-ore situation by the activities of Lake boats. The time was, and not very long ago, when the carrying capacity was about equal to the Lake movement. In fact, at times the carrying capacity of Lake ships, and especially the dock facilities, determined what the Lake movement of ore might be. That time is definitely past until the end of a long reconstruction period. There has been, through accident and otherwise, a loss in the actual number of boats navigating the Lakes, but this is far more offset by the increase in the size of the carriers. The larger boats which are now navigating the Lakes are able, on the draught permitted by the interlake channels, to carry easily 15,000 tons of any bulk commodity. Almost all of the new ships which have been built in the last four years have had a carrying capacity in excess of 10,000 tons. This constant increase in the size of ships, taken with an increase in speed of dock equipment, has given the Lake carrying fleet such an enormous capacity that it is almost out of the question for any reasonable movement of iron ore and other Lake commodities to keep the total equipment constantly employed. Thus if anyone had attempted to judge what the iron-ore shipments were for the last season by computing the running time of the Lake fleet, he would have come to the conclusion that the movement had been more nearly 250,000,000 than 32,000,000 tons. The fact was, that the boats got a late start because there was no demand for iron ore. Then they ran in haphazard fashion for a good part of the summer and stopped the movement of ore for some companies as early as the latter part of October. At no time was there any rush of equipment, and at no time was

the business even fairly active. In fact, the middle of the summer brought the remarkable situation that these great carriers were coming down the Lake in ballast instead of with ore cargoes, for the purpose of carrying coal back to the head of the Lakes; a thing which, in my thirteen years' association with Lake commerce, I have never known to have happened before.

The carrying capacity of the great fleet now available for Lake commerce is best illustrated by the fact that with a halting movement, with speed at no time attempted, with the boats of the Steel Corporation, in a large measure, in ordinary for a fair share of the time, the equipment moved easily the 32,000,000 tons of iron ore, 25,000,000 tons of coal, and proportionate tonnages of grain, lumber, and package freight. It is needless to say that this evidence of overproduction of Lake equipment has had a decided influence upon the shipbuilding industry, and has practically brought an end to the construction of new ships except those of smaller size which must trade at small and imperfectly improved ports. This has had a certain influence upon the steel business, since each one of the big ships contains upward of 5000 tons of finished steel. Practically no orders have been taken for the delivery of new boats next spring, and the state of affairs can be understood when I say that I remember one year when 42 new steel ships were constructed. This, for one small industry, means a considerable loss in steel consumption, and accounts for some of the reaction in the steel trade.

Last spring it began to look as though the steel business was in for a slight upturn in demand. Beginning at the bottom, efforts were made to readjust prices in such a way as to bring the buyers back into the market. The factors which controlled the iron-ore movement from the head of the Lakes decided to bring about a horizontal reduction of 50c. per ton in the price of ore to the furnaces. In pig-iron circles the influence of merchant furnaces had already been exerted to bring the price of No. 2 foundry iron to an average of below \$14 per ton in 'The Valleys.' Of course, this was not the minimum price, because the trade reports were teeming with suggestions that pig iron of this grade, to meet Southern competition, had gone as low as \$12, or even below that. At the same time, there had been a radical reduction in the price of coke. In a good many instances, the manufactured product was not bringing much more than the price of coal; not enough, surely, to cover the actual cost of conversion into coke. It was believed that, with this readjustment in the prices of raw material it would be possible to scale down in the prices of finished steel so as to invite timid buyers back into the market and possibly start a renewal of activity that would be beneficial to the country.

It is always easy, in attempting to explain why a thing did not materialize according to plans, to lay the blame principally upon the most conspicuous factor and to disregard other important factors which may be basic in their nature and therefore governing, while the others are superficial and of a sentimental effect only. Thus it is the easy thing to say that, just when all plans were being made for a revival in business, the Standard Oil and the American Tobacco Co. decisions were handed down by the U. S. Supreme Court, upsetting confidence and working through sentimental channels to the destruction of the promised prosperity in trade. It is easy to follow from this to the assault upon the United States Steel Corporation by the Government's legal department, and to say that this completely destroyed the confidence which business men and financiers were beginning to feel in the situation. Coming on the heels of that, were the assaults upon the lumber companies and associations, and similar actions against other large industries which were accused of violating the Sherman anti-trust act. I would not contend that these were not important factors, because they were. It may be nothing more than a coincidence, and again it may be highly significant, that the plans for larger trade were either annulled or suspended instantly following the announcements of these actions. From a broader economic standpoint, it is necessary to take into consideration other fac-

tors, and to make this point was one reason for dwelling upon the size of Lake ships and for dwelling upon other phases of the Lake carrying trade. Through the force of competitive effort, the Nation has, for a matter of almost a decade, been struggling to obtain economy, and, in order to reach that goal, has been constantly increasing the size of the producing and transporting units of industry. Emphasis has already been placed upon the increased size of Lake ships and their influence. The railroads have moved in the same direction by increasing the size of both ears and engines to move the larger units of freight to market. The steel mills have increased the size and productive capacity of single trains of rolls in order to get out more steel with the same plant and men as were employed formerly. Particularly, the coal mines of the East have done exactly the same thing. The size of mines has grown from 1000 to 3000 tons of daily output through a single shaft. With big producing units and with big transportation units, and the high speed of loading and unloading equipment, and no other market than that supplied by home consumers, it has been absolutely impossible for the country to absorb all that has been produced. It can easily be realized by the business interests that it is practically impossible to continue the old scale of prices and costs, and certainly it is impossible to expect to market the output if producing units are further increased in size, except through unhoped expansion of foreign trade.

All this gives particular point to the discussion which has been going on for the past year, and principally for the past six months, of the effect of certain National statutes and the need for radical revision. The fact of the matter seems to be that the country has reached a period where reconstruction is necessary, and this is toning down the activities of the country, regardless of any action on the part of Mr. Taft's administration in enforcing laws which inveigh against trade crimes. At the time this is written there is quite a general feeling all through the East that an expansion in trade may be expected on the first of January. It is impossible to say what is the hope at root in this matter, but it is a known fact that the hope is there. A few indications may tell precisely what is anticipated. In the first place, despite the enormous accumulation of iron ore from the Lake Superior region, assurances are given that the output will be increased next year. There is a slight tightening up in the pig-iron situation, and prices are firmer on future delivery than they have been for the entire year, with the exception of a short time in June and July. Also, for the past two or three weeks, reports have been coming in that consumers of coke are ready to abandon the open-market policy which has prevailed heretofore and are now willing to place contracts at existing prices for deliveries of considerable quantities over the first quarter, and even through the first half, of 1912. One representative of a company which is a large factor in the steel business, made the statement recently that his orders and inquiries for January and February delivery are heavier for either month than have been the sales for October, November, and December combined. A report from the East says that some of the steel mills at Philadelphia and Baltimore are expecting to resume activity by the first or fifteenth of January. Statements from the South or from the Birmingham district indicate the same condition. Knowing the need for readjustment along the fundamental lines previously outlined, my own disposition is to take these optimistic statements with a certain degree of allowance. I do not want to contend that the economic conditions, such as were outlined, are always and surely ruling factors in ordinary merchandising, but I do contend that, whether recognized or not, their influence, within certain limits, is powerful. It may be that certain constructive legislation at Washington this year will permit a gradual toning down of the great stress of competitive action and thus eliminate the need for a radical readjustment such as has been indicated. It is almost sure that some constructive legislation would have a large sentimental influence, at least upon the business situation, which now definitely needs some encouragement.

Gold-Dredging Industry on Seward Peninsula

By T. M. GIBSON

Such figures as I shall quote in this article are obtained in part directly from the management of the companies disussed, and in part from other sources, but I believe them to be close approximations to the truth. Solomon river is the oldest, and at present the most important, dredging district on Seward peninsula. Seven dredges have operated in this area this season and all have made satisfactory showings, while some have had quite phenomenal success.

The Three Friends dredge, now in its seventh season, was the first modern dredge installed on Seward peninsula. It has a 5-ft. close-connected bucket-line, and when running in gravel of a suitable depth has been able to maintain an average of 3300 cu. yd. per day for many consecutive days.

the Seward Dredging Co., that the consideration paid for the property was \$200,000, and the last payment must be made on or before January 1, 1912.

Mr. Halla informs me that the dredge has handled 200,000 cu. yd. so far this season, and that the cost, including amortization and winter care, is 18c. per cubic yard. He also said the gold content in his section of Solomon river is between 40 and 50c. per cubic yard. Mr. Halla will remain here this winter and will continue to operate the dredge as long as the weather conditions will permit. He says the company will probably build an electric plant near the mouth of Solomon river, early next season. This plant will cost about \$85,000 and will generate 1000 hp. It will burn

MINING LOCALITIES ON SEWARD PENINSULA.

It is a steam-driven machine and burns coal. Its power costs are perhaps the highest of all the dredges on the peninsula. It is equipped with simple slide-valve engines, exhausting into the open air, and its fuel consumption has been from 12 to 15 tons of coal per day. For many years coal cost about \$21 per ton at the dredge. I am informed that the price this year is \$19 per ton. It was the intention of the management to install a hydro-electric plant at the foot of Salmon lake, fifty miles distant, the year following the installation of the dredge, and thereafter run the dredge with electric power, but litigation over water rights, and other causes, prevented this plan from being carried out.

Last winter the Three Friends company sold this dredge, and a large tract of ground on lower Solomon river, to John A. Webb, who later transferred it to the Seward Dredging Co., an organization promoted by Mr. Webb and Otto Halla, both of Nome. This company was financed in the East, chiefly at Boston, and is a merger of the Nome Mining Trust and the Three Friends Mining Co. into one concern. It appears from the deed filed for record here, transferring the Three Friends Mining Co. holdings from Mr. Webb to

crude oil, and it is hoped thus to reduce the cost of handling gravel to 13c. per cubic yard. The depth of the gravel worked this season is about 7 ft. and the profitable area 600 to 800 ft. in width.

The Nome-Montana-New Mexico Co., operating a 5-ft. open-connected Risdon dredge on Solomon river, near the mouth of Shovel creek, has had a very successful season. This dredge is now in its fourth season and has been a money maker from the start. But heavy investments in a ditch scheme, with other complications, involved the company in considerable financial difficulty at the beginning of this season. J. P. Pearson was succeeded in the management by Dr. Ramsey, and a heavy indebtedness was wiped out by the end of the first month's run. The dredge now has about \$100,000 to its credit for this season. This boat is steam-driven, but, unlike the Three Friends, it has compound condensing engines and water-tube boilers, and consumes about one-half as much coal. Its actual operating costs do not exceed 12c. per cubic yard, but as there was only five years of work ahead of the dredge when it started the amortization charges are necessarily high.

Charles Kimball installed a 2½-ft. open-connected dredge, known as the sluice-box type, on Shovel creek this season. Shovel creek is a tributary of Solomon river, flowing in from the west side. It is well suited to a dredge of this type. The gravel is loose and free from clay, and is moderately coarse, though containing but few boulders of large size. The gold is coarse and easily saved. The gravel averages about 85c. per cubic yard. Mr. Kimball's dredge has neither screen, tailing-stacker, nor tables. The buckets dump on a grizzly, which cuts out the largest boulders and dumps them over the side, while the undersize drops into an ordinary sluice, which runs the length of the boat and projects about 20 ft. beyond the stern. It is driven by gas-engines and the sluice water is supplied by a 10-in. centrifugal pump.

The total cost of the dredge, when ready to run, was about \$18,000. It was landed on the ground early in July; was built and ready to operate by the middle of August, and has handled an average of 800 yd. per day for about 70 days. It has paid its expenses, its initial cost, and has a snug profit besides. Mr. Kimball has enough ground to keep it working six or seven years. In an article published in the *Mining and Scientific Press* last fall I emphasized the profitable nature of this class of investment on Seward peninsula, and while this area may be classed as among the very best, there are other good ones awaiting the enterprising dredge man of small means.

The Sivertsen & Johnson 2½-ft. Risdon dredge, built last year on Solomon river, made a rather poor beginning this season, but in the latter half of the season has been doing well. It worked through a shallow area having low gold content, but later reached good ground and will make a very creditable showing.

The Flodin Dredging Co., operating a Risdon dredge near the mouth of Big Hurrah creek, has had a very successful season. Mr. Flodin, the president and manager, has informed me that they have handled 130,000 cu. yd. this season, at actual digging cost of 11c. per yard. His repair bills have been pretty heavy this season, and these, with winter care and amortization, make his total charges considerably higher, though he was not prepared to say exactly what they are. He stated, however, that more than 50% of his gross output is net profit. His dredge has a 2½-ft. bucket-line and is steam-driven. The fuel used is coal, which costs \$20.50 per ton at the dredge. He has had a 130-day run this season, and closed October 28.

The Solomon Dredging Co., operating a 3½-ft. Bucyrus dredge near East Fork, on Solomon river, has had a splendid season. It handled approximately 160,000 cu. yd., and cleaned up about 70c. per yard from rim to rim of the river bed, which is about 300 ft. wide in this area. This company was promoted by Frank Reed, of Nome, in the winter of 1909-10. Some of the stock was taken by local people, but the majority is held in California. Henry Malloch, a California mining man, is the president and controlling stockholder. The dredge cost \$75,000, and the eight claims secured by Mr. Reed upon which to place the dredge cost \$16,000. The company has issued \$100,000 of its capital stock. The operating expense for this season is about \$30,000, and they have taken out about \$102,000 with a \$100,000 investment. This dredge was built last summer, and owing to delays in the delivery of machinery it was not completed until the freeze-up set in. Mr. Reed, who was then manager, started in and ran long enough to try it out, and then laid it up for the winter. At the annual meeting of the stockholders, Mr. Reed was retired from the management, and a brother of Mr. Malloch was elected in his stead, and the dredge has been run by him this summer. The dredge was equipped to burn crude oil, but for some reason coal has been used. Coal costs \$16.50 per ton landed at the coast, and \$6 per ton for a 12-mile haul on the Solomon River railroad, thus making it cost \$22.50 per ton at the dredge. Oil costs \$2 per barrel at the coast and \$10 per ton railway freight. Since 3½ bbl. of oil is equivalent in fuel value to 1 ton of coal, there would be a saving of \$5.50 per ton in the use of oil. The dredge was stopped for the sea-

son on October 19. The company has acreage enough ahead of the dredge to keep it digging four more seasons, and then it will reach a block of ground, consisting of 21 claims and covering about five miles of the river bed, which was lately purchased by the Pioneer Mining Co. for \$79,000, of which \$15,800 was cash and the remainder to be paid October 15, 1912.

The Wild Goose dredge, on upper Ophir creek in the Council district, leads all the dredges on Seward peninsula both in yardage and in value of output for this season. This is a 3½-ft. dredge of California type and was built by the Yuba Construction Co. It was installed last season, and was run about 10 days to try it out just before the freeze-up. Its power is supplied by a Standard gas-engine of 125 hp., which drives all machinery except the light plant, which has a separate engine of 6 hp. The dredge has now been running four months and will continue to run as long as the weather will permit. F. M. Ayre, general manager for the Wild Goose Mining & Trading Co., estimates the operating costs at 12c. per cubic yard for this season, but thinks it will be reduced to 10c. next season. Gilbert Russel has been in charge this season. This dredge used an average of 300 gal. of distillate per day, which cost 6c. per gal. in San Francisco; the combined ocean and river freight and wagon haul up Ophir creek to the dredge adds 17c. per gallon, making 23c. per gallon, corresponding to a total of \$73.60 per day for fuel. The dredge has handled an average of 2000 cu. yd. per day, and has had some phenomenally rich ground. As much as \$25,000 has been cleaned up for an eight-day run. It is not all as good as this, however, but the average has been above \$1000 per day for 120 days, so far this season. The first cost of the dredge was about \$80,000, a large part being freight.

The Blue Goose company's dredge on lower Ophir has had a much better season this year than last. It has worked through a portion of claim No. 3½, all of the Humbug Fraction, and a portion of No. 4 which the company holds under lease from the Wild Goose company. This is the oldest dredge on Seward peninsula now in operation. It was built by I. B. Hammond of Portland, Oregon, for Hernando De Soto, and installed on the Niukluk river just below Council City, in 1904. Hernando De Soto was unable to make it pay, and it passed into the hands of a receiver appointed by the court and by him sold to a company organized by local people, and called the Blue Goose Dredging Co. This company floated it up the river to a point opposite the foot of the valley of Ophir creek and worked across the intervening flats to Ophir creek, where it has worked successfully for the past five years. It has a 5-ft. open-connected bucket-line, shaking-screen, and belt-stacker. Almost every part of the machinery has been renewed, some of it several times, so that today, although it is old-fashioned in many respects, it is a staunch and strong dredge. It handles about 1000 cu. yd. per day, has about \$80,000 gross output to its credit this season, and is still running at this writing. It is a steam dredge and burns wood. This is laid down at the dredge for \$10 per cord. I have been unable to get figures as to the cost per yard for this season's run.

The Alaska Dredging Co., having one dredge on Gold Bottom creek and one on Warm creek, is reported by Jerry Wilson, the promoter and one of the heaviest stockholders of this company, to have had an excellent season. These are both 2½-ft. gas-driven dredges, and Mr. Wilson says they have averaged 1000 cu. yd. per day and the digging costs were 10c. per yard. It is said they are digging in ground that runs from 30 to 50c. per cubic yard, so it is evident they have made a profit.

The Kimball & Saupie sluice-box dredge, on Melsing creek, is reported to have kept up the high standard of work set last year, and the results of the season's work are highly satisfactory. This is a low-cost gas-driven dredge and is the type after which Charles Kimball's dredge on Shovel creek was made. On shallow creek bottoms having loose gravel and coarse heavy gold they are to be strongly commended, though they do not look as 'classy' as some of the other types.

Charles Lubby has installed a 2½-ft. dredge on Mystery creek, in Council district, this season. It was built by the Union Iron Works of San Francisco, and is said to have been built from the same patterns as the dredges of the Sioux-Alaska and Arctic Gold Dredging Co., which were designed by W. W. Johnson and installed in the Nome district last year. I have not visited this dredge, but if it is like the two mentioned, its bucket-line, trommel, and stacker are driven by a 50-hp. Standard gas-engine and its pump is driven by a 35-hp. Western gas-engine. It uses 150 gal. of distillate per day, has a crew of nine men, and its actual operating costs are about 10c. per cubic yard. This dredge was completed in August and has been running about 70 days. I am told it has handled about 1000 cu. yd. per day and that its owners are well pleased with the showing.

The Beardsley dredge, on Willow creek in Casa river district, has not been very successful this season. I am told, as compared with most other dredges on the peninsula, although Mr. Beardsley says his disappointment lies not so much in the returns upon the investment, which have been fairly remunerative, but in his failure to realize the im-

as if no spray were played upon it, so it seems probable that enlarging the perforations and reducing the pressure would increase the flow of water from a given sized pump and thereby increase the efficiency of the sluicing tables.

There are some spots of permanently frozen ground in the area being dredged by Mr. Plien, and he has found it necessary to cut through some of them. He has had a unique experience in thawing some of this ground with steam-points, and at a lower cost than has generally been thought possible. His gravel deposit is from 10 to 12 ft. thick and overlain by 1 to 2 ft. of muck and sod—an ideal deposit to thaw. If it were much deeper, the points would have to be too long and cumbersome to handle, and it is not likely that they could be kept vertical in penetrating the gravel, and if much shallower the yardage would probably be too small to pay to work unless it were especially rich. Mr. Plien mounted a 35-hp. boiler on heavy skids and covered it with light housing. This boiler supplied steam to a battery of 18 points. Crude oil was used for fuel, and the consumption was 300 gal. per day. The points were 12 ft. long and were set 6 ft. apart in a line covering

ON THE BEACH OF NOME IN WINTER.

mense profits that he anticipated when he went into the enterprise. He stopped work early in October, as Willow creek does not furnish water for flotation after the first frosty weather sets in.

In the Nome district the dredges have had a busy season and have met with a fair degree of success in most cases. The Plien Mining & Dredging Co., having a 3½-ft. Risdon dredge on Otter creek, has had a satisfactory season. For several reasons the yardage was much less than the theoretical capacity of the dredge, but Mr. Plien tells me that the ground is good enough to make up for the low capacity. The dredge has only averaged about 1000 cu. yd. per day, and it is rated at 2000 yd. The low efficiency is due in part to a high percentage of heavy sand in the material, making it difficult to wash, and in part to an insufficient amount of sluice water. This is, perhaps, the weakest point in every dredge on the peninsula. Nearly every one of them can dig more material than it can wash, and the chief reason why they cannot wash more gravel is because their pumps do not give them sufficient water. Larger pumps should be installed with a given sized bucket than has been the practice. Possibly if the perforations in the spray-pipe were made larger, thus reducing the back pressure on the pumps, the difficulty might be overcome. There is no cemented gravel to be disintegrated by the action of the screen and spray, and I notice that wherever a dredge strikes a bed of clay, it passes through the screen and out over the stacker in balls a foot or more in diameter, just

about 100 ft. The next line was 6 ft. back, and the points were set so that each was midway between the points in the line in front. Steaming was continued for 20 hours. It was found that this overthawed the space between points, so it was widened to 7 ft. and the lines of holes made 7 ft. apart. Repeated tests show that this is the correct distance for most economical work. To set the points requires two men and consumes about two hours time. The roustabout from the dredge aids the point man in this work, and then goes back to his regular duties. There is one point man on the day shift and one on the night shift, and each works 12 hours. Crude oil costs \$2.85 per barrel, delivered. The plant is moved ahead from time to time by means of a long cable passing through a sheave anchored ahead. By this system Mr. Plien thawed 20,000 cu. yd. at a total cost of \$2000, or 10c. per cubic yard. These figures allow for wear on points, hose, and other equipment, and for use of the boiler, but do not cover the whole cost of this equipment. This work has demonstrated the feasibility of working shallow frozen deposits, which are conveniently situated, at a total working cost of 22½c. per cubic yard. Mr. Plien tells me his operating costs are \$125 per day, or 12½c. per yard on 1000 cu. yd. daily average.

It must not be understood that these figures apply to all depths of frozen ground, nor to all localities where gold may be found in permanently frozen ground. With greater depth of ground it becomes increasingly difficult to penetrate it with points. It is impossible to control the direc-

tion of a long slender point in ground containing coarse material, and a limit is soon reached below which it is economically impossible to thaw by any known method. Nor would Mr. Plien's figures apply to interior points, where the cost of fuel is prohibitive. Mr. Plien tells me that this season's run has enabled him to pay off obligations of the company amounting to \$20,000, and, in addition to this, a substantial dividend to the stockholders. This is certainly a satisfactory result.

The Saunders Dredging Co., which was organized here last year to take over the machinery for a dredge which had been shipped here for the Gold Beach Dredging Co., and which was held for freight and certain charges which the company were unable to meet has, at last, after overcoming many obstacles, completed the construction of its boat and launched it on what is hoped will prove a long and successful life. It was thought by A. Anderson, the manager for the Saunders Dredging Co. when this plant was taken over, that he was getting a high-class Bucyrus dredge, and he was much chagrined to find, after the dredge was delivered at the ground upon which it was to operate, that the only parts the Bucyrus company had built were the bucket-line, tumblers, and driving gear, and the balance of the machinery had been bought from various houses and selected by a man who had but little knowledge of the requirements, and therefore, as might have been expected, the machinery, other than the Bucyrus equipment, was little else than an aggregation of misfits and unbalanced parts. Many thousands of dollars had to be spent in the purchase of new machinery and in making changes in the first lot. The machinery was landed on the ground about the middle of last summer, and it was not until the middle of this summer that it began to run, although every effort was made to hurry the work along. The dredge has now closed for the season, after 45 days of running, and Mr. Anderson is going outside to purchase additional material. He says after the contemplated changes are made he will have as good a dredge of its size as any in the country. None of his winch friction clutches worked satisfactorily, and his main-drive winch friction would not work at all. If he wanted to stop his bucket-line it was necessary to stop the engine driving it. Fortunately he is digging to a false bottom of marine sand and there are no large boulders in the deposit, so that this was not so dangerous as it might otherwise have been. Mr. Anderson will buy new friction clutches of a different make. The shaft in his winch-drums were too small and all were broken as soon as put under strain. He had larger shafts turned, and the drums re-bored in a local machine shop, but this has weakened the stock in the hub of the drums so that he will replace them next season with new ones. His stacker ladder is 36 ft. long and he will lengthen it 10 ft. next spring. He has already lengthened his digging ladder by inserting a 9-ft. section. In the 45 days he ran, he handled about 60,000 cu. yd. He has Metz & Weiss gas-engines and burns 200 gal. of distillate per day. By investing \$1600 in 200 oil-drums, he is able to lay his oil down at the boat for about 14c. per gallon. He figures his actual digging cost at about 10c. per cubic yard.

The Arctic Gold Dredging Co., running a 2½-ft. gas-driven dredge on Grass creek, has run all summer without a hitch or stop. This dredge was designed by W. W. Johnson and built by the Union Construction Co. in San Francisco. It was installed last season and has had a remarkably successful record as a digger up to the present time. The bucket-line, trommel, and conveyor are driven by a 50-hp. Standard gas-engine, and the pump is driven by a 35-hp. Western engine. Mr. Middaugh, the manager, tells me that he has handled about 130,000 cu. yd. this season, digging 130 days. The dredge burns 150 gal. of distillate per day and the total operating expense is \$105 per day. No time has been lost on account of repairs this season, and the repair bills are practically nothing. Mr. Middaugh says he has the best little dredge in the North, but is sorry he did not put it on richer ground. There is still a long stretch of the Grass valley ahead of him, and he hopes to find the ground better as he goes up the creek.

The Sioux Alaska Dredging Co., having a sister boat to the Grass creek boat, and operating on Moss gulch, has had plenty of trouble this year, working down grade in a gulch that has a 9% gradient. The dredge worked upstream last year, and Mr. Murray, the manager, thought his worst troubles would be over when he reached the upper limit and turned to come back, but in this he was much disappointed. He has found it necessary to build dams about 100 ft. in advance of the dredge and to raise the water-level 5 to 7 ft. in order to get flotation. These dams were made of timber, and about 10,000 ft. of lumber was required for a dam. While digging to one dam he would be building another, and having reached the first one, he would allow the water to escape into the next dam, and then remove the first. His dredge has been aground repeatedly, but he has managed to get down the gulch 800 or 900 ft., and is now in flatter ground, and his "winter of discontent" has been "made glorious summer" by striking some phenomenally rich ground that makes up for his lost time.

The Gold Beach dredge, which was built two years ago on lower Dry creek, in an area almost all of which is permanently frozen, was dismantled last winter and hauled 12 miles to Osborn creek, and was there rebuilt early this summer. It has a 5-ft. open-connected bucket-line and is steam-driven. Its fuel is crude oil, of which it burns 30 bbl. per day. The moving of this dredge 12 miles across country, over the snow-covered hills and valleys, was no small matter. The total weight of the dredge is about 300 tons. It was moved by the C. L. Morris Transfer Co., under contract. The dredge company had to dismantle and rebuild it.

After the machinery was removed, the caps were taken from the gantries and the hull was sawed into two equal parts, from the well to the stern. These hull sections were the most difficult to haul. They were jacked up and placed on two sets of heavy round timber skids, fore and aft, and the skids were firmly chained together. A section weighed 55 tons and was drawn by 66 head of horses. The whole thing was successfully landed on Osborn, and the two parts of the hull were brought together and firmly bolted by a series of rods running clear across the boat. The joint was heavily reinforced with timber, and it is claimed that the hull is as strong and rigid as ever. The machinery was replaced and the dredge was ready to work when the season opened. It has not been smooth sailing, however, as unexpected difficulties have been met. The ground contains many large boulders, which are difficult to handle. The dredge was started in an area that had already been worked over, and it was found that a much larger proportion of the gold had been mined than had been supposed. The dredge ran behind, and creditors finally became so insistent that the company turned it over to a group of creditors, headed by Joe Montgomery of the C. L. Morris Transfer Co., under whose management the boat is now operating. It has worked its way out of the old tailing piles and is now in good ground. Mr. Montgomery tells me that a further three weeks' run will pay all indebtedness, and the dredge will be handed back to the company, which may yet realize a profit on what has been a very badly managed enterprise.

A new dredge was installed on Osborn creek this season by the Julien Dredging Co., of which V. A. Julien is president and manager. This dredge has a 3-ft. open-connected bucket-line, revolving screen, and belt-stacker. A 50-hp. Standard gas-engine drives the bucket-line, screen, and stacker, and a 30-hp. Standard engine drives the pump. There is also a 6-hp. engine that runs the electric-light plant. These engines use 160 gal. of distillate per day. This boat was designed by W. W. Johnson and H. G. Peake, of the Union Construction Co., and was erected under the personal supervision of Mr. Johnson. The dredge construction began on June, and was completed and ready to run July 21. It has now run 100 days and has handled an average of 1000 cu. yd. per day, or a total of 100,000 cu. yd. this season. This dredge cost \$43,700 when complete and ready to run.

Mining Conditions in the South of Spain

By HENRY F. COLLINS

At the urgent request of a valued friend I have been induced to write this article, of a type that I dislike. When produced spontaneously, such articles are usually written by comparatively green graduates on the strength of two or three years' residence in a foreign country, often confined to a single district, in the course of which period they have associated as much as possible with their own countrymen and as little as possible with the natives of that in which they are temporarily resident, whose language they have not troubled to master, and whom, consciously or unconsciously, they despise as beings of an inferior order. The more intimate is one's knowledge of a country, the greater the diffidence felt in generalizing about it.

One predominating feature in the conditions is the fact that, compared with the mining regions of Spanish America and many of those in the United States itself, Spain is a highly civilized country. I do not mean 'civilized' in the sense that every adult or even every child enjoys the blessing of being able to read, say, the Sunday edition of the *New York Herald*, for the proportion of illiterate is still, alas, high; nor that all important towns enjoy the benefits of railroad communication, for in old countries towns came ages before railroads, and not afterward. I merely wish to recall the fact that Spain was the most civilized country in the world centuries before those twin pioneers, the 'shooting-iron' and the whisky-bottle, overran the Wild West, and long before the Pilgrim Fathers were, through an obstinate narrow-mindedness at least as great as their own, driven forth to seek a New England across the Atlantic. Since that date and up to the present Spain has assimilated most of the manifestations of modern progress.

Civilization, of course, has its drawbacks as well as its advantages. It is not possible, for instance, in Spain, as it is in many parts of Spanish America (or was a very few years ago), when the stock of ore in the bins is running low, to lay by the heels on Saturday night in the company's lock-up a gang of trammers in order to have them ready fresh and sober on Sunday morning, and so prevent a stoppage of mill or smelter; nor is it always possible to get one's own foreman or clerk appointed Justice of the Peace or Police Commissary. It is not even possible, as in some more favored countries, for the mere possessor of unlimited cash without any political influence, properly so-called, to buy outright a Board of Supervisors, or of Aldermen, or a State Senate. On the other side of the account must be set the fact of comparatively good communications, there being a large number of State-owned macadamized roads for wheeled traffic, uniting important towns and villages even in districts not served by railroads. It is always possible, moreover, even in such remote districts, to contract locally for supplies of every variety, timber and other materials of construction, as well as for all kinds of surface work, excavation, and grading, and it is easy to get (at comparatively low wages) skilled artisans of all kinds who are always ready to feed themselves, even if it be necessary in uninhabited regions to house them and start a store. It is therefore never necessary—as in many parts of Central and even of North America—to commence operations by importing at heavy expense skilled workmen with every kind of material required for building houses for them, to put up boarding-houses, and in some cases to import beasts of burden to handle the company's traffic over the newly built road to the mines, and even the very fodder for these to eat, or to erect saw-mills and lime and brick-kilns; such pioneer work having been done centuries ago.

Spain counts for little at present in the progress of nations, and there is nothing brilliant in her immediate future; but she has at least a great and glorious past; its heritage still overshadows the land, and its traditions still mold, not indeed the everyday life of the people, for that

is dependent upon their present necessities, but their instincts, their deportment, and to a great extent their mode of thought, and their resultant actions. Do a Spaniard an injury or put an affront upon him, and he will move heaven and earth to wipe out that affront or to repay with compound interest that injury, if it should take him ten years. Do him a trifling favor and he is yours to command, never satisfied until he has found opportunities of repaying your favor ten times over. Everything that is good in the country, including this exaggerated conception of personal honor, has been handed down from a remote past; with the exception of indolence, ingrained in the race, practically all the evil is of comparatively modern growth, and the socialistic and revolutionary propaganda so much in evidence lately, is purely exotic, having its origin across the Pyrenees.

So long as the feudal system remained a living reality, Spain was a prosperous and a progressive country; it was only when all power became centralized in a corrupt court under the control of ecclesiastical dignitaries, and the close feudal relationship between the great nobility and their dependents degenerated into absentee landlordism (the curse of Spain today as it is of Ireland) that stagnation began, owing to the withdrawal from the rural districts of the element which stood at once for capital, intelligence, and initiative. After the departure of those who should be the natural leaders and rulers in the rural districts, there ensued the development of the present political system, under which local middle-class busybodies and third-rate professional politicians become the agents and henchmen of the party that happens to be in power in Madrid, and control not only the elections, but also the appointment of local authorities, judicial as well as administrative, with the result that exceptionally good codes of laws and bodies of regulations are administered capriciously, the principle of equality before the law being often set aside in favor of private interests, and still more often in favor of political influence.

This does not apply as regards the administration of regulations affecting the mining industry by officials directly responsible to the central Government. The regulations themselves indeed often appear to be vexatious in the complexity of detail which they prescribe, and but little discretionary power is vested in the officials who have to carry them out, but the latter are as a rule reasonable and obliging (more so, in fact, than those of some other countries that might be mentioned) and if treated with due courtesy will invariably be found willing to concede all the facilities possible, and to exercise their discretion in such fashion as to cause the minimum amount of inconvenience.

More especially is this the case as regards the corps of mining engineers, whose duties comprise not only the inspection of mines but all matters concerning the survey and granting of mining concessions and subsequent modification of the grants, questions affecting conflicting rights under different concessions, and the investigation of all cases in which the interests of the mining industry appear to clash with rights of individuals, of corporations, or of the State. For, as in all Spanish America, where mining laws were based on the Spanish law and have followed pretty closely successive changes in the latter, minerals (with certain specified exceptions reserved to the owner of the soil) belong to the State, by whom concession of the right to work them is granted upon definite conditions, chief among which is regular payment of the annual rent.

In the execution of their duties the official mining engineers are hampered by detailed regulations, which, as usually happens with Government regulations in all countries, have been drawn up by officials who are not always in touch with the practical working conditions under which

the industry is carried on. However, as a body, they are cultured, well intentioned, and conspicuously honorable, and within the limits imposed upon them by official red-tape they do their best to oil the wheels and to enforce the law with as little hindrance as possible to the mining companies.

Labor Conditions.—The Spanish workman is, as a rule, sober, steady, and industrious, if under proper supervision; frugal, partly from necessity, he is almost always cheerful, generous to a fault, and improvident in the extreme. His efficiency, under proper control and supervision, is high, and, considering his poor feeding, surprisingly so. Per unit of wages earned, the Spanish miner does more work than any other in existence, save perhaps the Piedmontese and the Hungarian; for his wages are low, the standard rate of day's pay throughout the south of Spain being about 3.5 *pesetas* (say 64c.) per day. This, of course, is only the nominal rate, for practically all are on contract, and the average wage earned is about 85c., out of which each man has to find his own illuminant, either olive oil or acetylene. Laborers at surface earn 45 to 50c.; underground trammers, etc., 55 to 70, or 75c. on contract. At such prices it is not surprising that these efficient workers operate, for instance, in the Spanish pyritic mines, at a cost which under equal conditions as to hardness of ore, complete extraction without loss, and complete filling of excavations, would be utterly impossible in America. The American miner, whether native-born or of foreign nationality, although doubtless somewhat more efficient, man for man, than the smaller and less well nourished Spaniard, is by no means sufficiently better to offset the much higher wages paid in America.

The Spanish miner in the south does not keep nearly as many feast-days as are observed by other classes of workers, particularly in the towns; being sober, he misses fewer Mondays than do most miners in northern climes; moreover, he is always ready to work on Sundays or to do over-time when required at the ordinary rate of pay. So long as he is treated with scrupulous fairness by chiefs whom he can respect for their strict justice and good example, he does not mind being handled firmly; in fact, like the school-boy he appreciates the firm hand when sufficiently discriminating, his unconscious ideal of good government approximating to the paternal or patriarchal. What he most dislikes is to be treated as a mere unit or as "one of the hands" by an unsympathetic superior who not only does not know his name or anything about him, but does not care to find out. This partly explains the undoubted fact that the smaller concerns, in which there is more direct intercourse between individual workers and their chiefs, are able, other things being equal, to get more work done, man for man, than the large companies, even while paying the same wages. Unionism, already a great evil in the north and east, has made no progress in the south, where the more capable of the workers fully recognize that their own exertions will suffice to bring them to the top and keep them there, and do not see why they should be 'levelled down' to the standard set by the less capable. In the north and east of Spain conditions are unfortunately different, partly owing to influences from across the Pyrenees that have been at work for a long while, and possibly also to less consideration for their work-people as individuals on the part of the large companies doing business there.

Methods of Working.—Timber being scarce and dear, and it being considered in Europe inadmissible to leave behind in a mine ore upon which there is even a small margin over the cost of extraction and treatment, it is necessary in the case of almost all lodes and orebodies to employ a system of complete extraction of the ore-shoot with filling of the excavation, except in districts like Linares where comparatively narrow and almost vertical lodes cut through hard granite with good solid walls, in which case filling of the excavations is to a great extent unnecessary, such portions of the lodes as are too poor for removal affording the required support. In a few cases where the lode or pay-streak is narrow and the ore rich, it is worked

by 'stripping' or 'resneing', one of the walls being first blasted down and waste material thus obtained sufficient to fill the excavation. In the case of wide lodes and masses, like those of iron ore and the pyritic deposits of the provinces of Huelva and Seville, filling has, of course, to be brought in from outside. Even if the cost of timber did not prohibit the use of square sets, that method would be considered barbarous, as indeed it is. Caving methods do not appear to be applicable when it is essential that the ore should be taken out completely without loss, and without any admixture with waste, even 1% of which mixed with the ore would have a serious effect upon the selling value; moreover, the danger of premature leaching, and the still more serious danger of spontaneous ignition through the heat generated by crushing, are insuperable objections to caving methods as applied to cupriferous pyrite. Complete extraction and filling therefore is the only practicable method under the conditions.

Up to widths of 30 to 40 ft. pyritic lodes are generally mined in successive horizontal cuts 2 metres high and the full width of the lode, the filling being kept some way behind or close up, according as the ore stands well or the reverse. With wider lodes, say, 40 to 75 ft., the method is varied, and often alternate blocks on each temporary level are taken out transversely from the foot-wall across to the hanging, and filled before attacking the intermediate blocks. In short wide orebodies a cut is sometimes taken out from the foot-wall side half-way across for nearly the full length, and filled; a temporary level being established down the middle, the remainder of the cut is then taken out in alternate blocks, each block being cut out first along the hanging wall from the cross-cuts and thence backward to the central temporary level, followed by the filling put in through the same cross-cuts. In one case, of a long and wide orebody, a central tramping level is established upon each floor and from it the ore is taken out right and left in alternate blocks to hanging and foot-walls respectively. These blocks being filled, the alternate ones are attacked and when the whole is cut out, over a height of 2 to 2½ metres, a working level is established on the filling, parallel to the tramping level and one set to either side of it. The next cut is taken out in similar fashion.

The most satisfactory way of mining pyritic masses that are both long and very wide (150 to 450 ft.) has still to be determined. The system of cutting out vertical sections right across from wall to wall on several floors successively, the empty space being filled, with strong masonry walls to support the filling, has been tried and found wanting. No ordinary masonry is capable of sustaining the enormous pressure over such a width; moreover, the localized pressure and movement are often so great as to give rise to spontaneous combustion of the pyrite. At one well known mine where hitherto the work has been done by open-cuts, and where the problem of working by underground mining a mass of ore from 200 to 400 ft. wide is only just being attacked, the method adopted is to take out first only a section along the centre, 75 ft. wide, by means of successive continuous horizontal cuts running the full width and followed by filling in the ordinary fashion, as if the orebody were only 75 ft. wide, the idea being that after some years the filling in the central section will become sufficiently consolidated to permit extracting the remaining side sections by means of transverse horizontal cuts, removal of the foot-wall section presumably preceding that of the hanging-wall part.

The upper zone of all the wide pyritic masses that outcrop or approach the surface is removed by quarrying, the cost of removing the overburden to uncover the ore averaging from 3 to 17 *pesetas* per cubic metre of rock in place, according as it consists of soft easily broken slate or of hard solid 'porphyry' or other igneous rocks. The point at which it ceases to be profitable to remove overburden in order to quarry the ore varies with a number of factors, but in general terms it may be said that provided the rock to be removed does not amount to more than 1 to 2 cubic metres per ton of ore rendered available, it is always worth while to strip, since the resulting

amortization charge of 3 to 5 *pesetas* per ton for removal of overburden is less than the extra cost of breaking underground as against breaking in the open, plus the cost of filling. In special cases it may be worth while to remove even as much as $2\frac{1}{2}$ to 3 cubic metres of solid rock per ton of ore uncovered, but that is about the limit, unless it is a case of getting at ore that has been robbed or partly worked by the old system of pillars, the cost of getting which by any system of underground mining would be much greater than in the case of a virgin lode.

Fiscal Exactions.—The financial contributions levied upon the mining industry are extremely onerous. A producing mine, in addition to general stamps and other duties and taxation paid by everybody, has to pay the following taxes:

(1) Surface claim tax on the area covered by its mining claims, amounting to 6 *pesetas* per hectare in the case of iron and 15 *pesetas* per hectare in the case of other metals.

(2) Land tax on any freehold land.

(3) House tax on all or any buildings.

(4) Industrial tax on each of its workshops separately, namely, carpenters, blacksmiths, etc., etc. In the case of a company owning a workshop with machine-tools driven by steam or other power, assessment may be made, as in the case of a factory, on spare parts of machinery. The tax then levied is heavy, being at the rate of 200 *pesetas* per year per horse-power of the motor installed for driving purposes, whether or not that power be fully occupied. Fortunately there is no uniformity of assessment, and workshops are not always taxed under this head.

(5) Income tax at 10% in some cases and 5% in others on all salaries of employees. These amounts may be collected from the employees if the company so chooses, but in the case of most foreign companies it is not customary to do so. In any case the company is responsible for payment direct, whether it collects or not. This tax is levied not only on employees resident in the country, but on the salaries and fees paid to directors, auditors, consulting engineers, and other head-office employees; in fact, on all who draw fees or bonuses of any description from the company, wherever they may be employed.

(6) Profits tax at the rate of 2% upon the amount of all dividends declared.

(7) Tax on capital. This tax, logically quite indefensible, is levied at the rate of one mil on the total nominal capital of the company, or upon the total estimated value of its property and assets of every description, as determined by a special investigation conducted by the Government officials *ad hoc*, whichever gives the highest figure! The object being merely to squeeze out as much revenue as possible, regardless of equity and logic. If one company has a large watered nominal capital, they charge on that, and if the assets of another company are worth far more than its nominal capital, so that the shares stand at a high premium, they charge on their valuation of the assets.

(8) Transport tax. 5% upon the amounts paid for transport of all products by rail, in addition to another 5% collected by the Government direct from the railway company; this the latter adds to every way-bill, thus making in all 10%, which the producer pays the Government over and above whatever is charged by the railway for moving his ores and supplies.

(9) Export tax. This is levied on most kinds of ores and metallurgical products, some of the principal items scheduled being the following:

Description.	<i>Pesetas</i> per ton.
Iron ores	0.25
Pyrite with less than $2\frac{1}{2}\%$ copper.....	0.25
Ores with more than $2\frac{1}{2}\%$ copper.....	1.60
Ores of manganese.....	0.50
Ores of lead.....	15.00
Argentiferous lead	10.00
Copper matte	20.00

The duties on ores of lead, argentiferous lead, and copper matte have, of course, for their object encouragement to

undertake smelting and refining in the country.

(10) Three per cent production tax. This tax is levied on the gross value of the product as it leaves the mine, and is calculated by deducting from the sale-price the bare cost of transport and handling between the mine and the market where sold. In the case of Spanish iron ore and pyrite, the margin of profit on which is so low, the 3% of the gross value of the output at the mine often amounts to as much as 15 to 20% of the working profit on mining the ore, and in some cases it may be more than the whole of the working profit.

Production of Electricity.—Every mine that generates electricity, even for its own consumption, has to pay a tax, which, however, is only one-half the amount of that charged to a company producing electricity for sale. The rates are 0.50 *peseta* per kilowatt-hour on current for power purposes and 6.75 *pesetas* on current for lighting purposes.

In addition to the production tax on electricity, that used for lighting is also taxed separately, whether or not the current is produced by the consumer for his own use. It should further be noted that all machinery and the bulk of the raw material used by the mining industry, including coal, coke, railway material, wagons, constructional ironwork, explosives, lubricants, illuminants, and tools of all kinds, pay exorbitant import duties. Explosives and petroleum, indeed, are protected monopolies, and, as always happens in such cases, not only are the prices exorbitant, but the quality is bad. Certain kinds of machinery and supplies, including pig and wrought iron, are produced in the country, but except as regards constructional ironwork, which is good and cheap, the prices are in most cases practically the same as those of the imported articles, the duties merely serving to enrich local manufacturers, who, as in some other countries, arrange the tariffs to suit their own interest.

In the case of the smaller pyritic mines of the provinces of Huelva and Seville, the total amount of Government taxation varies from 15 to 30% of the gross value of the ore per ton f.o.b. the shipping port, or, which amounts to the same thing, from 20 to 40% of the value of the ore at the mouth of the mine. This is a crushing load of taxation for any industry to bear, and it will be readily understood that it presses with exceptional weight upon those mines in which, owing to the poverty of the ore, small size of the orebodies, distance from the shipping port, or other incidental circumstances, the working costs bear a higher ratio than usual to the value of the product. In quite a number of such cases indeed it snuffs out the profit altogether, and fiscal exactions transform what might be a small working profit into a substantial loss.

Blinded by the prosperity of Rio Tinto, which is able to stand these and almost any imaginable fiscal exaction, the Spanish Government, with its continual proposals for the increase of taxation and the indiscriminating way in which this is levied, is seriously hampering the development of the smaller mines and impeding the influx of capital to still undeveloped properties. Such a policy appears to be short-sighted.

Copper Surplus

Figures showing the visible supply of copper at the beginning of each month are now widely available. Below are given the amounts, in pounds, known to be available at the first of each of the last six months of 1911, with certain other months for comparison.

Japan's Mineral Production

By H. FOSTER BAIN

Statistics of the mineral production of Japan in 1911 will not be available for some months. The figures for 1910 are given below:

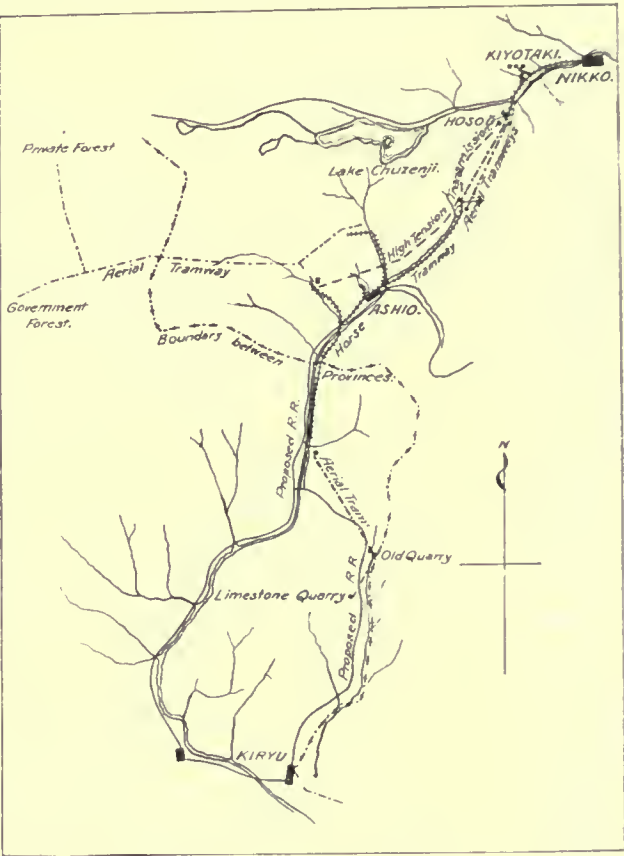

MINERAL PRODUCTION OF JAPAN, 1910

	Amount.	Value, yen.

It will be noted that the total mineral output was worth \$50,000,000, of which one-half was derived from the collieries, a trifle over one-fourth from the copper mines, and the remainder divided among petroleum, gold, silver, pig iron, sulphur, pyrite, lead, zinc, and minor items. A review of the figures for the past ten years shows a consistent and gratifying increase in output and value. In 1900 the total was \$24,633,727; this had doubled by 1906. Increases since have been offset by decreases in price.

The coal-mining industry continues in a flourishing condition despite the competition of the Manchurian and Chinese mines. In Japan the great bulk of the coal mined comes from the southern island, Kyushu. Here the Chiku-Ho districts produce 52½% of the coal output of the Empire and show a steady increase in output. Contrary to a widespread impression, the known reserves are increasing rather than decreasing, deep drilling having resulted in enlarging the known field. At the well known Takashima colliery of the Mitsn Bishi Co., additional beds of coal have been found, and the engineers of that company now estimate the reserve at 160,000,000 tons; enough to continue the production of 2000 tons per day for over 200 years. Throughout this field large modern collieries with steel top works, excellent pumps, and turbo-electric power stations are to be seen. One interesting feature of the district is the Meiji Higher Technical School recently founded to give secondary instruction in mining and related branches of engineering. It is endowed with 3,000,000 yen by one of the successful coal-mine operators, and is directed by Naka Matoba, formerly of the Engineering College of the Imperial University at Tokyo. Instruction in the higher branches of engineering is also now provided by the Kyushu Imperial University at Fukuoka, where Y. Watanabe, who will be remembered by many American engineers as having been at St. Louis in 1904, is now stationed. A little farther south, at Omuta, is the Miike colliery, the largest in Japan. It alone produces nearly one-eighth of the output of the Empire. The Mitsui firm, to which it belongs, produces, altogether, a sixth of the total output. Of this about one-fourth is exported, aside from that sold as bunker coal. The Miike

collieries include six working pits, the deepest and most important being the Manda. This pit has two shafts 930 ft. deep, the larger being 12 by 41 ft. in cross-section. The output from this shaft is 2200 tons per day, and for the whole field 12 tons of water must be pumped to raise one ton of coal. There are many interesting features of the mine equipment and mining practice at this point that must be left for later description, but here, as at the other large mines of the Empire, every advantage has been taken of latest improvements in plant and methods. Coke is made at present in beehive ovens, but a bank of Koppel ovens is now being built, and all by-products are to be saved. At present but half the gas is used, but with the new plant two 2000-kw. gas-engines will be included, to drive electric generators, supplementing the three 5000-kw. Curtis turbo-generators now in use. The total pumping equipment when complete will be capable of handling 22,500 gal. of water per minute from a depth of 1000 ft.

SURFACE MAP AT ASHIO.

An excellent harbor with tidal lock has been built and equipped with three Miike loaders, each capable of handling 5000 tons per hour. The use of mechanical loaders is in line with modern progress, but does away with one of the picturesque features of a stop in Japan, coaling ship by hand. In the latter work the Japanese have become expert. At Nagasaki, the Mitsui Bishi Co. in 1902 put 1210 tons of coal on the *Empress of China* in 3¼ hours; at a rate of 372 tons per hour. At Yawata, where coal is loaded by hand, the cost is about 17½¢. per ton; each workman handling two tons at a daily average wage of 35¢. It is against such labor costs that machinery must compete in the Far East. In northern Japan large coal deposits are being developed in Hokkaido. The output now equals about 10% of that of the Empire and is rapidly growing. Examinations made this year by Japanese engineers have extended the limits of the known field and developed the presence of especially valuable gas coals. Arrangements are being made to open additional mines. The coal industry in Japan is conducted on a satisfactory basis of profit. Costs are not notably different from those in the United States, good coal being produced as low as \$1 per ton at the pit mouth, and averaging, in 1910, \$1.61. Selling prices, however, are better, much coal bringing \$4 to \$4.50 per ton. Roughly, it may be calculated

that excellent Japanese coal can be laid down profitably in San Francisco, duty paid, at about the same price as American and Canadian coals are now delivered, namely, \$6 to \$6.50 per ton. Actually the Pacific Mail boats use Japanese coal on the east-bound trip, and, except when cargo space is at a premium, bring over enough to burn on the return trip.

Aside from coal, Japan produces petroleum, though not as yet in large quantity. In 1910 the output was 182,000 bbl. The production has not varied greatly for five years, and general opinion is to the effect that large oilfields are

MANDA PIT AT MIIKE COLLIERY.

not likely to be developed, except possibly in Saghalin. Prospecting there is under way. Charcoal remains the main fuel for domestic purposes throughout Japan, though in time coal may be expected to largely supplant this, as it has already done in manufacturing, and in heating the larger modern houses.

Next to coal the most important mineral mined in Japan is copper. The total output in 1910 was 111,780,058 metric tons, and in 1911 will doubtless be larger.¹ While there are a large number of copper mines, three have been de-

ARTIFICIAL GARDEN MADE FROM THE SCRAP PILE AT SUMITOMO SMELTING WORKS ON THE OCCASION OF THE VISIT OF THE AMERICAN ENGINEERS.

veloped on so large a scale as to overshadow the others. These are the Kosaka, of the Fujita firm; the Ashio, of the Furukawa firm; and the Besshi, belonging to the Sumitomo firm. The Kosaka, 400 miles north of Tokyo, has been for several years the largest metal mine in the Far East. In 1908 it yielded nearly 16,000,000 lb. of copper, with 1,000,000 oz. silver. Work has been conducted on a large scale with both open pit and underground mining and pyritic smelting. Because of the presence of much barite, the ore is especially refractory, but the metallurgists in charge succeeded in overcoming all difficulties. This mine seems now to have passed its prime, unless additional orebodies be found, and at present the leading pro-

ducer is the Ashio, where 600 metric tons of metallic copper per month is produced from ore averaging 3% copper produced in two grades; smelting ore with 12%, and concentrating 1%, brought up to 12% by milling. Ten years supply is reported to be available. The general situation and work at this mine have already been described.² In 1910 and 1911 important improvements were made, and others are under way. A railway is now being built to the mines, the dressing works at the mouth of the Tsudo adit are being enlarged, a new Ingersoll-Rand class P compressor with air-cylinders 16½ and 27½ by 24 in. has been put into service, and many other changes made. At Nikko additional water-power has been developed, and the refinery is now being enlarged to double its present capacity. In the new plant the multiple instead of series system will be used. At the Besshi mine, which in 1911 will probably rank first in production—though between any two of the three big mines there is little difference—important improvements are also under way. Up to this year steam-electric power has been used at the mine, but a new 3000-kw. hydro-electric plant is now nearly completed. An unusual feature of this work is that the water is brought from the east side of the mountain through the mine by way of the Hiura adit. It has a total fall of 1975 ft. and 25 cu. ft. per minute is available. A new adit 15,000 ft. long is now being driven to undercut the present workings 1876 ft., and to meet it a round shaft,

BLAST-FURNACE AND STOVES AT THE IMPERIAL STEEL WORKS.

16 ft. in diameter, is being sunk from inside the mine. It is interesting to note that this work is being undertaken without preliminary testing of the lower ground, because of the confidence engendered by the persistence of the ore-shoot, which is 5000 ft. long, to the present working depth of 2000 ft. The average content of the Besshi ore is 10% Cu, and it is so free from deleterious substances that no refinery is necessary. To avoid their introduction into the matter, a barren flux is used in place of the usual gold-quartz ore. Within the year briquetting has been abandoned in favor of pot-roasting, and a unique method of nodulizing the fine ore preliminary to roasting has been developed by Keijiro Nakamura, superintendent of the Sumitomo smelting works at Shisakajima. A number of other improvements are being made, and an excellent future may be safely predicted for this mine. In addition to the three big mines mentioned, there are many others less well developed, a number of which may be expected to become important producers. At present Japan exports copper to the amount of about 80,000,000 lb. per year. While wire, sheet, and pipe plants are in operation and are being rapidly enlarged, it is probable that exports will continue to increase. Japanese companies are able to work copper up into finished products and supply the local market, including the demand incident to a rapid expansion of trolley roads now just beginning, and still export metal. Since the balance of trade is against Japan and foodstuffs in particular must continue to be imported, the mineral products form a natural means of payment for imports not covered by silk and tea while manufactures and shipping are being developed. While costs of copper

¹For review of the copper production of Japan in 1910, see T. Haga, *Mining and Scientific Press*, June 24, 1910.

²Read, T. T., *Mining and Scientific Press*, October 14.

production are not published in Japan, as in the United States, it is evident that they do not differ greatly from those in America, though possibly lower. At the Ashio, against heavy pumping charges, and with all the usual smoke trouble, it is possible to work a 1% copper ore in narrow veins and concentrate it in mills much smaller than those working on similar ores in the United States.

Gold and silver form a much less important element in the mineral output of Japan than in the United States. Of the former the annual production is now about 150,000 and of the latter 4,500,000 oz. Gold mining is, however, increasing, though the placers have proved disappointing. For this metal the Japanese look to Chosen, or Korea, where both old and new mines are being developed on a large scale by both Japanese and foreigners. The principal Korean gold mines have been repeatedly described in the *Mining and Scientific Press*. Within the year steady progress was made at the Oriental Consolidated and other properties. Difficulties between the Japanese and American interests at Chieksan have been adjusted, and, in addition to quartz mining, the placer ground is now being tested. Farther north, Japanese engineers have been drilling placer ground with such encouraging results that it is expected that a dredge will be ordered within this year.

In iron and steel, 1910 marked a turning point for Japan, in that, for the first time, the Imperial works at Yawata showed a profit. This has stimulated the industry, and extensive building is under way both at Yawata and in Hokkaido, where English and Japanese are coöperating in developing private iron and steel works. At the Imperial works the foundation has been laid for an additional blast-furnace designed to increase the capacity 250 tons per day. A more significant event, possibly, is the development of adequate supplies of ore within the limits of the Empire. When the works were established it was necessary to import ore from central China, and even now approximately half the supply is brought from the Tayeh mine. Since, in accordance with the general tendency in mining and metallurgy in Japan, the works were established for the prime purpose of rendering the Empire independent of foreign producers, the disadvantage of this arrangement is obvious. Persistent effort has led to the development of iron ore of 50% grade in Hokkaido and at other points in Japan proper, and the opening of considerable bodies of ore analyzing 52 to 62% Fe, much of it bessemer grade, in Chosen or Korea. At present a considerable amount of ore is coming from these mines, and this is likely to be greatly increased since the Mitsu Bishi Co. has taken important leases in the district.

It may also be noted that among the less important industries of Japan, zinc mining is rapidly growing. The present ore production amounts to about 25,000 tons, the result of five years development. An interesting feature of the industry has been the development of a flotation process which is being successfully applied at the Kanioka mine of the Mitsui company. Not content with producing ore only, the Japanese are already planning to build a zinc smelter, and in a few years may be expected to supply their own needs for spelter. At present zinc to the value of \$1,000,000 is annually imported.

Any general review of the year would be incomplete without some reference to the visit of the Empire of the party from the American Institute of Mining Engineers and the generous welcome extended to them by local members, the mine-owners, and the Mining Institute of Japan. The memory of the meeting will always remain pleasant to everyone who took part. In 1899 when, on the initiative of the United States, Japan was invited to join the international conference regarding the seal fisheries, the event was referred to as 'Japan's coming-out party.' In a certain sense the meeting of the mining engineers in Japan this year was similar, since for the first time the local mining industry was thrown open to the full review of a large and representative body of foreign engineers, and for the first time, in any large way, a body of professional men visited the mines to carry away ideas and new methods in practice.

Mining Industry in Italy in 1911

By CHARLES WILL WRIGHT

The statistical reports from the metal mines in Italy for 1911 will not be available for six months or more, and only a few general conclusions as to the results of the present year can be given. The statistical reports for 1910 have recently been published in the *Revista del Servizio Minerario*, and these are referred to in the present review in order to show the relative importance and progress made in various phases of the Italian mining industry up to this year. The sulphur mines in Sicily are of greatest importance. The zinc-lead mines in Sardinia rank next in value of output, and these are followed by the iron mines on the island of Elba. Then follow the quicksilver mines, the pyrite mines, and the copper mines. Other metals, including manganese, antimony, gold, silver, and tin, are produced in small quantities.

SULPHUR

The output of sulphur during 1910 was 2,815,511 tons, with an average of 30.03% sulphur. The total value of this product was 32,383,409 lire,* or 11.50 l. per ton. A total of 23,063 workmen were employed in these mines, the average wage being 2.37 l. per day. These figures compared with those for 1909 show a slight decrease in output, though an increase in the tenor of the product and a decrease in labor, with an increase in wages of 0.17 l. per day. Electric power is being introduced in these mines for hoisting and transport. During 1911 there was a further decrease in labor, though the output will probably compare well with that of 1910. In recent years no new discoveries of sulphur mines have been made, nor in the methods of ore treatment were there any improvements.

A review of the statistics shows that the sulphur output during the past 10 years has decreased from an average annual production during 1900-1905 of 3,659,819 tons, valued at 42,946,717 l., to an average production during 1906-1910 of 2,910,515 tons, valued at 32,882,770 l. This decrease in recent years is attributed largely to the increased output of silver in the United States, principally from the mines of the Union Sulphur Co. in Louisiana. In 1910 Sicily produced 92% of the total sulphur output, the remaining 8% being derived from the mines in the districts of Bologna and Naples. The output of commercial sulphur in 1910 from Sicily amounted to 394,812 tons, and the exportation was 393,987 tons. The estimate of the stock of sulphur in Sicily at the end of 1910 was 640,647 tons. The value per ton of commercial sulphur during 1910 was 96.97 l. Of the sulphur exported in 1910, 50% went to Germany, 13% to America, 10% to Holland, 9% to England, and 6% to Austria.

LEAD AND ZINC

Nearly all of the mines producing lead also produce a considerable amount of zinc, and conversely. All of the lead ores contain from 100 to 1000 grams of silver per ton. The total lead output in 1910 was 36,540 tons, containing 80% lead and 400 gm. silver, and valued at 145 l. per ton, or at total value of 5,303,855 l. This shows a decrease of 1405 tons and 453,036 l. from that of 1909. The decrease was attributed to the unfavorable market price for lead. In 1911, on the other hand, the market has been more favorable, and exploration for lead ore has been energetically carried on at many of the mines, and the lead output materially increased. The lead ores consist of about two-thirds galena and one-third carbonate ore.

The zinc output in 1910 was 146,307 tons, averaging 37.76% zinc, and valued at 101.18 l., or a total value of 14,803,100 l. This exceeded the 1909 output by 16,408 tons and 2,298,698 l. This rate of increase has continued during 1911, and for this year the totals will probably show a considerable increase over 1910. The cause of this increase is attributed largely to the steady increase in the

*The *lira* (l.) is worth \$0.193.

market price for zinc. About 70% of the ore produced was calamine and smithsonite ore, and 30% blende ore. The largest producing lead-zinc mines are in the Iglesias district of Sardinia, and include the Monteponi mines, the Buggersu mine belonging to the Malfidano company, the Giennamari-Ingurtosu mines, the Pertusola mines, and those of the Vielle Montagne company. Other mines of importance are Argentaria, Nebida, Masna, and Rosas.

The Iglesias district produced 95% of the total lead-zinc output in Italy. The remaining 5% came principally from small lead mines in the province of Bergamo. The total labor employed in the lead-zinc mines of the Iglesias district during 1910 was 12,598, or a decrease of 475 from the total for 1909, though the output was increased by 8853 tons. In 1911 a similar decrease in labor will be recorded, with a corresponding decrease in the output. This shows increased efficiency in labor, though the results are also due in part to the introduction of rock-drills and improvements in the mechanical treatment of the ores. It is also to be noted that the miners' wages are gradually being increased, the present average being about 2.45 l. per day.

A comparison of the output from the lead-zinc mines during 1901-1905 shows an average annual output of 188,837 tons, valued at 22,240,252 l., and during the years 1906-1910 the average was 190 to 382 tons, valued at 23,075,782 l. The zinc production has been increased during recent years, and it is probable that this increase will be continued, as new reserves continue to be opened up. The lead production, on the other hand, has decreased in late years and no new lead mines have been developed.

SMELTERS

There are two lead smelters in Italy; the Pertusola smelter at Spezia and the Monteponi smelter in Sardinia. During 1910 the Pertusola smelter was shut down for a few months in order to introduce various improvements, including two Dwight-Lloyd converters. A total of 21,070 tons of ore was treated, and 11,500 tons of commercial lead and 12,000 kg. silver produced. In 1911 the amount of ore treated will approximate 30,000 tons. The Monteponi smelter produced, in 1910, 2995 tons of commercial lead and 2237 kg. of silver. At this plant a new process for making zinc oxide from low-grade ores is used.

IRON

The production from the iron mines in Italy during 1910 was 551,259 tons, containing 53% iron, and valued at 7,619,031 l., or 13.82 l. per ton. Of this amount, 532,671 tons was produced from the Elba mines, the remainder being from small iron mines in Sardinia and the province of Bergamo. These figures show an increase of 49,898 tons above the 1909 output, which was entirely from Elba.

The iron mines on the island of Elba are leased from the Italian Government by the Societa Elba, and their maximum production has been fixed at 500,000 tons per year. The ore is mined entirely by surface workings, and these are connected by overhead cable trams with bins at sea-level from which the steamers are loaded. The ore consists of hematite and limonite, and is especially free from impurities. The ore is supplied almost entirely to Italian iron and steel companies. There were 1571 men employed at the Elba mines in 1910. During 1911 there was a serious strike for some months at these mines, but because of the large stocks of ore at the mines it is not believed that the output will be materially decreased.

QUICKSILVER

The product of this metal is from cinnabar ores derived chiefly from the mines of Monte Amiato in the district of Florence. These mines produced, in 1910, 87,129 tons of ore containing 1.04% Hg and valued at 3,729,352 l. Some 70,000 tons of this ore was treated, and a yield of 893 tons of quicksilver, valued at 5,358,000 l., obtained. These mines employ 994 workmen. The statistics show an increase in output to the value of 128,704 l. over 1909. No marked change is anticipated in the output of quicksilver in 1911. A small amount of this metal, usually less than

one ton, is produced annually as a by-product at the Monteponi smelter in Sardinia.

COPPER

The copper mines produced 68,369 tons of ore in 1910, containing 2.96% copper and valued at 1,036,674 l. Of this output, 58,989 tons, valued at 677,193 l., was from the mines in the province of Grosseto in Tuscany, the remainder from small mines in the provinces of Genoa and Torino. The totals are 21,963 tons and 866,733 l. less than in 1909. During 1911 these mines have continued to keep up production as in 1910, but the general decline is attributed to the fall in the market price of copper. Developments are in progress on copper deposits in Sardinia, though these will not be producing for a few years.

PYRITE

The production of pyrite is becoming an important industry in Italy, and during 1910 there was a considerable increase over 1909 in the output. A still greater increase is expected in 1911, as researches have been advanced at the Miniera Vallebria and Miniera di Gavorranno, and aerial trams installed for the transport of ore. In 1910, 135,628 tons of pyrite was produced, containing 44.62% sulphur, and valued at 16.97 l. per ton, or a total of 2,301,851 l. Besides this, 30,060 tons of cupriferous pyrite, with 1.51% copper and valued at 562,680 l., was produced. These figures represent an increase over 1909 in the total value of product of 663,515 l. The pyrite mines employed 1809 workmen in 1910, and in 1911 about twice this number are being employed.

MANGANESE

The manganese output comes essentially from the Liguria Gambatesa and Nascio-Monte Bianca mines in the province of Genoa, the Monte Argentario mine in Grosseto province, and the Capo Becco and Capo Rosso mines in Sardinia. The total output in 1910 was 29,900 tons of ore, valued at 314,179 l., a decrease from 1909 of 55,601 l. in value. The 1911 production will probably show a slight increase over 1910.

ANTIMONY

The output of this metal showed a large decrease in 1910, though in 1911 the production may show some improvement. The entire production, 2194 tons, containing 25% antimony, and valued at 149,769 l., was derived from the mines in Sardinia, Lu Laergin and Corti Rosas. The decrease in 1910 from the output in 1909 amounted to a total value of 61,851 l., though the tonnage produced was greater.

GOLD, SILVER, AND TIN

These metals are produced only in relatively small quantities in Italy. The total value of the gold output was but 58,730 l., and this was derived principally from the Valbianca mine in the province of Turin. The ore is pyritiferous quartz. The only productive silver mine in Italy is the Giovanni Bonu mine, near Monte Narba in Sardinia, and from this but 32 tons was produced in 1910, carrying 1.53% silver, and valued at 42,400 l., a decrease of 25,400 l. from 1909. The main silver production is derived from the lead mines already mentioned. No new discoveries of gold or silver deposits were made in 1911. There is also one tin mine in Italy; the Monte Valerio, in the province of Pisa. At this mine exploration is proceeding, principally by diamond-drilling. The output in 1910, which amounted to 170 tons, valued at 41,000 l., was derived by the re-treatment of the old dumps.

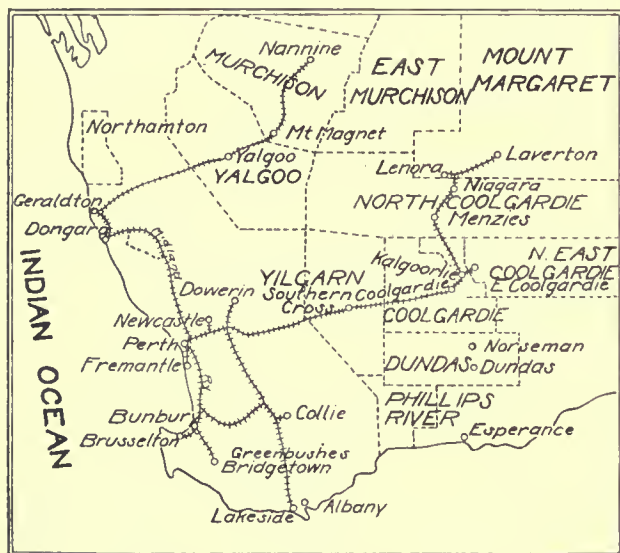

Anthracite Coal Shipments

(Figures in long tons, December 1911, estimated.)

	1911.	1910.
January	5,904,117	5,306,618
April	5,804,915	6,244,396
July	4,804,065	5,202,059
October	6,269,179	5,622,005
Total	70,000,000	64,905,786

Australasian Mining in 1911

The year 1911 was one of unexampled prosperity in Australia. Since 1902-3 the whole country has enjoyed a run of good seasons. The general prosperity of the world, the advance in industry, and the extension of civilization, especially in the East, have been responsible for an ever-increasing demand for the leading products of this country. The greatest recovery has been in the pastoral industry, which, after seven years of drought, is now in a condition hardly ever before approached. It therefore can be said that as far as the great staple products, such as wool and wheat, are concerned, Australian wealth has been immensely added to, by the largeness of the yields and the splendid prices realized in the world's markets. But while good seasons have placed the pastoralist and the farmer on their feet, they have unfortunately not helped the mining industry of the country. When times are bad in Australia the instinct of the community is to go back to mining. When times are good, labor drifts to agricultural pursuits, to orcharding and to dairy farming. The withdrawal of labor for these industries during the past two years has been very great, and it has had the

WESTERN AUSTRALIAN MINING DISTRICTS.

effect not only of closing a number of low-grade mines, but of restricting the prospecting operations in the great unknown districts in the centre of the continent. Therefore the year 1910-11 closed without the discovery of any new field of importance.

Twelve months ago, as will be recalled, it was hoped that the Bullfinch district, near Kalgoorlie in Western Australia, was to provide a second 'Golden Mile'. All that the rush there did was to prove the utter worthlessness of nearly every claim that was floated. The parent property today languishes, and there are not a few who declare that its fate is sealed. The effect of that ill-considered boom was to tighten the purse-strings of a large part of the public and to discourage prospecting in other districts. Western Australia, as far as the Eastern States go, is a name which is associated with heavy losses, and therefore investment in that great tract of country is small and on the most cautious lines. The Kalgoorlie district has nothing fresh to show. Its mines are pushing ahead with work at depth, the leader being the Great Boulder. The stability of the property is marvelous. It is altogether over capitalized, but the mine has developed exceedingly well at different points. While it may be doubted whether the ore reserves exposed equal the value indicated by the market price of the shares, still such confidence is felt in the management and in the general outlook of the property that the claim holds its own in public estimation, not only as a gold mine, but as a pioneer at depth. Taking the leading ventures at Kalgoorlie, it is to be confessed

that the majority of them at depth show signs of impoverishment. In the outside districts of the State, little that is encouraging can be stated. A number of small mines are being opened, and everyone lives in the hope that some happy find will once more bring Western Australian mining to the front, but indications today are not stimulating. One of the troubles of the country, of course, is the dryness of the interior. Prospecting means really exploring under the most adverse conditions. A man going out into the arid back territory carries his life in his hands, and with capital shy there has been a shortage in the number of prospectors who are prepared to undergo personal hardship for possible future gain. Another thing that tells against the industry is the exceedingly high price of labor. This is due to the introduction of Wages Boards, which allots a set wage to the miner, and on such a liberal basis that it means the keeping closed of a great number of low-grade mines. A Labor Ministry has just been returned to power in the State Legislature, and it is hardly likely, therefore, that relief from this direction will come to the mining industry. In the northeastern part of the State, it was hoped that the Tanami field would develop satisfactorily. A proved deposit is known just over the border in South Australian territory, but the conditions there are so adverse that, while large bodies of moderate grade gold-bearing material exist, the cost of transport, the difficulty of obtaining water, and the exceedingly high price of labor, have meant that the locality has been deserted excepting by a few.

Taking the Eastern States, the Victorian gold yield unfortunately disclosed a fairly large shrinkage. This arises mainly from the exhaustion of a great number of the deep lead alluvial mines of the State. The famous Creswick district, which yielded millions of pounds worth of gold, is now almost deserted. The magnificent machinery and plant of one of the leaders of the famous Berry group has just been sold. This means that, with the exception of the South Berry company, not a mine is now working on this once famous gutter. At Rutherglen—another important alluvial field—two mines remain out of the big group that once existed there. English capitalists tested ground at the Southern & Prentice, but abandoned the claim after large sums of money had been sunk. Now it would appear that, in the Chiltern field, another property, that within a short time has yielded over £1,100,000 worth of gold, is likely to close down. This would mean that only one mine would remain in this district. The cause of the trouble has been the impossibility of getting an adequate supply of competent labor. Miners have been allured from mining to agricultural pursuits by the high scale of wages offered and the more pleasing conditions of work, or they have been attracted to the State coal mine at Woathaggi. In addition, in the lower levels of the deep-leads system, the average value of the ground is considerably less than nearer the surface. Alluvial mining is conducted at a depth of over 400 ft. below the surface, and as water is heavy, costs are high. With scant and poorly qualified labor available, with heavy charges for pumping, and lower gold returns, it is not to be wondered at that alluvial mining is going a good deal out of favor.

The district that is saving the situation is Ararat, where, in some of the tributaries of the Lange Logan system, rich gold is being obtained. The quartz-mining industry is also being affected by the absence of new discoveries. Great mines, like the Long Tunnel, find the gold content of the ore decreasing as depth is attained. The same thing has happened at Bendigo and Ballarat. At Bendigo what is known as the 'side lines' of saddle formation are worked. They are entitled to be called main lines, as it is from them that the bulk of the gold so far has been mined. In one of these side lines, 'the Sheephead', at a shallow depth, rich gold was found, and the discovery has stimulated the whole field. There are ten or twelve undeveloped lines available for exploration. An old field that has shown very satisfactory signs of revival is Daylesford. There the formations are flat bodies of quartz

running into the slate from vertical lodes. The distinct geological conformation of the country puzzled the old generation of miners. As it now seems to be better understood, mining men set out with the definite object of picking out these flat bodies and not troubling their heads about vertical lodes. The result is that several fine mines have been opened, and there is every promise of the number of these being increased.

In New South Wales a great part of the State's industry is coal-mining. Unfortunately the coal miner is about the most unsettled being on the face of the earth, and in this respect Newcastle has its peek of troubles each week. Sometimes it is the miners, other times the boys or the wheelers who cause mischief. The vast extent of the Greta seam and the size of other coal measures in the State, make coal mining under almost any conditions profitable, but there are signs that the development of the coal measures of Queensland, and the dependence that Victoria is placing on its State coal mine at Woathaggi, will affect trade in Newcastle coal. A good deal of wonder is also expressed as to whether, when the Panama Canal is opened, British coal, or coal from the Eastern States of America, will cut out Australian coal from the market it now enjoys on the eastern coast of South America and also at San Francisco. A considerable quantity of Newcastle coal goes to Chile and Peru, and it would be a great blow to the New South Wales industry to lose this market.

Copper mining in New South Wales has not gone ahead. The greatest claim there is the Great Cobar, but from one cause or another the mine has not done well of late years. What is badly needed is an increase in the price of the metal. Tin mining also is on the down grade for the reason that most of the alluvial deposits are worked out. No gold mines of any importance exist in the country, but to Victorians a most interesting piece of work is being conducted in the Wellington district. Out that way rich gold leads were worked to shallow depths by the old miners, and then abandoned. Ballarat capitalists experienced in deep-lead mining are testing the gutters there, and, in one instance at least, have been rewarded with exceptionally profitable results. It is not beyond the region of a probability that a new goldfield will be developed there.

The most promising development of the year has been made at Broken Hill. There the British mine, which was floated in 1886, by the Broken Hill Proprietary Co., for £500,000, and has ever since been more or less of a waster, appeared to be on its last legs. Boring just done in a block of the ground which alone remained untested has exposed the presence of a magnificent shoot of ore. This has been proved from 900 ft. to within 200 ft. of the surface. Now the outlook for the mine is as bright as that of almost any property on the field. A visit paid quite recently by the mining editor of the *Argos* (Melbourne) resulted in some exceedingly interesting figures being published as to the reserves of ore in the field. It came as a surprise to most people to find that, although mining on a huge scale has gone on incessantly at Broken Hill since 1886, the reserves are larger today than they were five years ago. The following table gives the figures:

ORE RESERVES AT BROKEN HILL

	1906.	1911.	Ore treated
	Tons.	Tons.	yearly.
			Tons.
Proprietary	3,500,000	2,250,000	125,000
Block 10	1,000,000	555,000	100,000
Central	3,623,000	3,600,000	230,000
South	1,400,000	3,500,000	330,000
South Blocks	100,000	500,000	120,000
North	600,000	1,500,000	260,000
Junction	200,000	300,000
Junction North	124,000	350,000	150,000
British	600,000	800,000	150,000
Block 14	220,000	220,000
	11,667,000	13,475,000	

The grade of ore at depth is certainly decreasing, but

the field has a magnificent record, as is to be seen by the following figures:

	Authorized capital.	Value output.	Divs. and bonuses to end 1910.
Proprietary	£ 384,000	£33,051,904	£9,848,000
Block 14	155,000	3,286,136	459,827
British	264,000	2,071,243	337,500
Block 10	1,000,000	368,729	1,235,000
Sulphide	1,100,000	11,142,907	797,500
South	200,000	3,620,500	755,000
North	175,000	1,469,487	291,440
Junction	100,000	813,055	85,000
Junction North	180,000	960,401	43,793
South Blocks	200,000	525,176	10,000
South Extended (formerly A. H. B. Consols)	337,500	150,344	50,000

The most remarkable recent development has been in connection with the zinc industry. The flotation process has revolutionized the field, the result being that the income obtained from zinc products has meant a doubling of the returns to shareholders. The way that that branch of the industry has gone ahead is illustrated by the statement that Broken Hill now supplies the world with a sixth of its zinc requirements. This yield is almost exclusively in the hands of the German buyers, although the Broken Hill Proprietary Co. is smelting zinc on a small scale at Port Pirie.

Mining in Queensland has, on the whole, not been altogether satisfactory. The big goldfields there, too, are on the wane, for with depth poor ores are being obtained. On the other hand, the copper-mining industry is developing most satisfactorily. Mount Morgan is becoming more and more a copper producer. In the north around Cloncurry, British capital has developed several undoubtedly fine copper mines, and it is no exaggeration to say that within a short time this part of Australia will be turning out more copper than any other district on the continent. The Chillagoe field has been a disappointment, and the chief English company that controls the interests there, is extending its influence to the Etheridge field, where it is opening up a number of gold and other claims. Tin and wolfram are other products and are being mined on a fair scale, but old deposits are being worked, and these will gradually be mined out. Striking evidence is being furnished that Queensland has great coal measures, and as time goes on, this branch of the mining industry is sure to receive attention. Unfortunately, at present the population is so sparse that the coal seams lie idle.

New Zealand mining has suffered through the cutting out of gold at depth in the Waihi mine. Operation at the State coal mine resulted in a loss for the last year. Generally speaking, the mining industry there is flat. An attempt is being made to prove whether oil exists in New Zealand, but so far without any striking results.

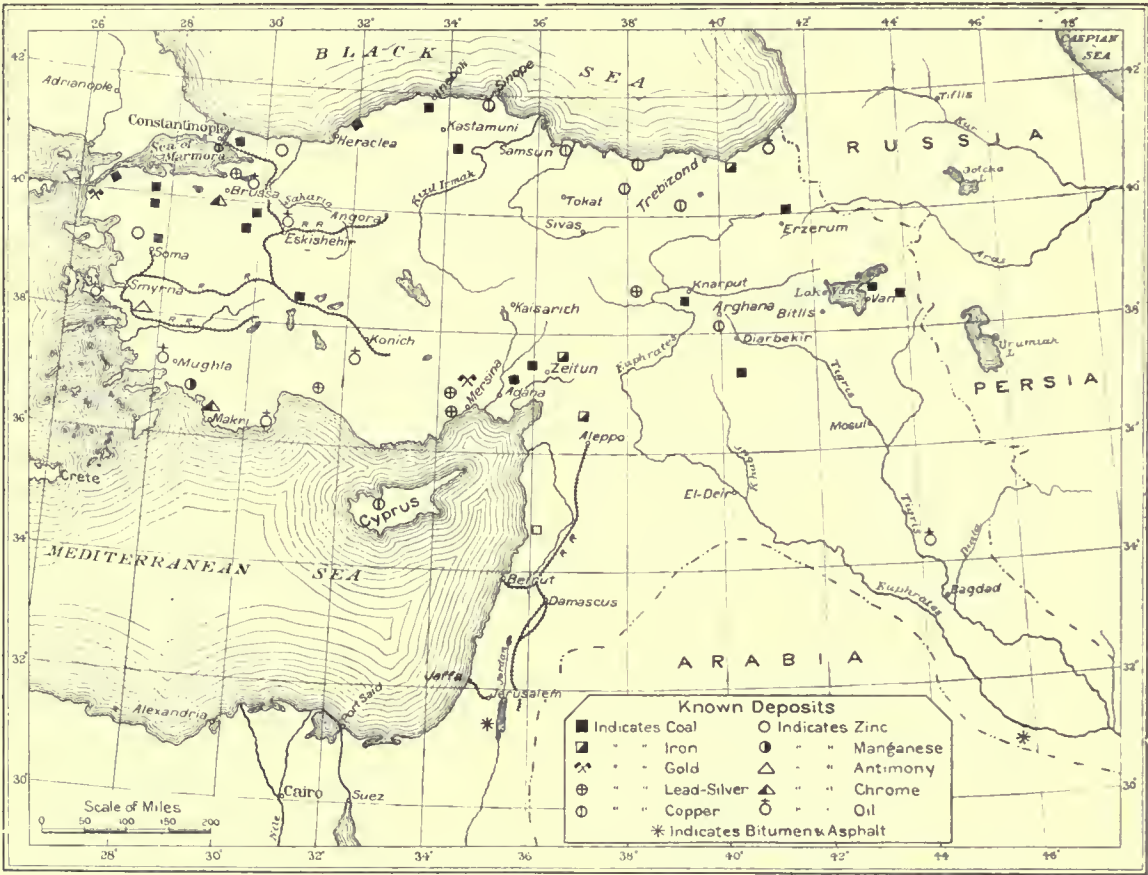

As regards mining in Tasmania, the leading mine, the Mount Lyell, is temporarily under a cloud through the miners having gone out on a strike. The most prominent of the men's several grievances is that contract parties have been allowed to work longer shifts than eight hours, thus breaking away from the eight-hour system. Also, they ask for increased wages. Seeing the small margin of profit made last year, it is difficult to see how much increase in wages can be granted, unless some improvement in the price of copper is forthcoming. The men were out on strike nearly three months. As regards the mine itself, the property looks well, and good ore is being won. The amalgamation of the Mount Lyell with the North Lyell mines in 1903 has been the salvation of both properties, as the basic ore of the one concern serves as a natural smelting flux of the silicious material of the other. The tin-mining industry has been fairly well maintained, and the ample supply of water on most of the properties has permitted uninterrupted work. The biggest disappointment in Tasmanian mining was the falling away in the amount of gold in the ore in the lower levels.

Mining in Turkey in 1911

By LEON DOMINIAN

The growing attention bestowed on prospecting and exploration work constituted the most noteworthy feature for 1911 in the Turkish mining industry. It is now realized in that country that possibilities of wealth exist in the resources of the subsoil, and this added to the newly-telt beneficial effects of a liberal government has led to active prospecting. In previous years it often happened that the prospector's toil went to naught, as his discoveries were usually taken over arbitrarily by some one of the privileged few who stood well with Abdul Hamid. Fortunately, this form of nepotism has disappeared since the downfall of this monarch, and a more equitable state of affairs now exists. The bulk of this exploration work

Somewhat farther east of Anamur, near the seaport of Mersina, and still broadly speaking within the same mineralized area, chrome-ore mines will probably yield about 2000 tons. The ore is of a good grade, containing 51 to 53% chromic oxide. Most of it is shipped, after a rough sorting, to Germany, although a small amount is usually reserved for French buyers. The price paid f.o.b. steamers is in the vicinity of \$19.50 per ton. Considerably north of these deposits, in the valley of the Olympus, another chrome-ore mine is operated at Adranos by a Smyrna company. The production for 1911 will probably amount to about 15,000 tons. The ore is higher in grade at this point, assays often giving 55% chromic oxide. It is shipped to the seaport of Ghenmlek at a distance of 90 km. from the mine. During 1911 practically all of the transportation was performed by means of wagons instead of the camels which were formerly used. The ore was disposed of as usual, a large tonnage going to Germany.

KNOWN MINERAL DEPOSITS IN TURKEY.

has been accomplished by the natives. It is yet in its infancy, when compared to our knowledge of the country's mineral resources. The larger companies, most of which are foreign, have been content with gathering information from the natives, and it is only in a few cases that they have made show of sufficient interest to actually undertake anything else than general reconnaissances. Asia Minor has been the scene of the greatest activity in this direction, and, as might be expected, the more accessible regions of the coast-land have received a larger share of attention than the inland districts. In the vicinity of Anamur, on the Mediterranean, about 30,000 tons of iron ore has been mined by an Anglo-French company, in the course of its investigation of a region from which promising reports emanate. This district lies at the foot of the southernmost projection of the base of the Tauric region, where various ores are reported to occur and within which mining has been carried on in a desultory fashion for over twenty centuries. A zinc mine in a very early stage of development is also operated by the same company in the same district, and its output was expected to reach 2000 tons in the year. Here, as with all other producers in Turkey, accurate yearly returns are not yet available.

Operating expenses at this locality are stated to be as follows, per metric ton:

Mining	\$1.00
Taxes	2.30
Management	0.40
Export tax and miscellaneous wharfing charges	0.23
Loading on steamers	0.46

The selling price of this ore is based on a 50% assay plus a payment of Fr. 3.10 (\$0.62) for every additional per cent of chromic oxide. At this price the costs tabulated immediately above allowed a margin of profit of about \$6 per ton, on the roughly sorted ore laid f.o.b. steamers during the year. Another chrome-ore mine in Asia Minor, situated at Karlyer near Inegheul, produced about 2000 tons, under practically the same conditions as those found in the Adranos deposits. The ore here averages about 50% chromic oxide. It is probable, however, that a careful sorting would increase the tenor of the product shipped. Some work was also undertaken by English capitalists in the vicinity of Aleppo, where high-grade chrome ores have been discovered. A deposit which is stated to run high

in chromic oxide was discovered during the year in the vicinity of Arsous, not far from Aintab, northeast of the previously mentioned place. Development was actively carried on in this locality, and the first shipments are expected to be made early in 1912.

The most important of all the chrome-ore deposits worked in Asia Minor occur at Dagħ Ardi near Broussa. The production for 1911 is estimated to exceed 15,000 metric tons. The ore occurs in large masses and irregular blocks in serpentine, and is sacked without further handling as it comes out of the mine. In this condition it usually assays 56% chromic oxide. It is transported on camel-back (a camel will carry 100 to 250 kg. of ore—228 to 570 lb.—according to the nature of the country traversed, the smaller amount constituting the limit for mountainous localities) for a distance of 70 km. or about a three days' journey, to the railroad station of Kutahia, whence it is routed over the Anatolian railway to the seaport of Derinidje, near Ismid. Here it is transferred to steamers and is shipped to one of the following harbors: Glasgow, Liverpool, Antwerp, Rotterdam, Hamburg, Havre, Marseilles, Philadelphia, Baltimore, or New York. It is usual to figure 5 camels to a ton of ore for the trip from the mine to the railway station, and the cost per ton laid f.o.b. steamers varies between \$7 and \$9, these being the lowest figures for this kind of ore in Turkey. In the European section of the country, mention must be made of the chrome-ore deposits of Orachia, lying close to the Salonica-Uskub railroad. Their production will probably attain about 1000 tons, all of which are shipped to Austria. Some exploratory work was also carried on at Radieha and Caranza near the town of Uskub, as well as near Tikmesh.

The meerschaum mines in the vicinity of Eski-Cheir were operated by the Government during the year as usual. Their production will probably amount to 250 metric tons, valued at about \$500,000. This is probably the most important deposit of its kind in the world. The mine lies at a distance of about 22 km. from the railroad station, to which the ore is packed by camel-trains. The deposit occurs in a valley filled with drift material from the surrounding mountains. The sepiolite is scattered through the drift in rounded nodular masses with fragments of magnesian and hornblende rocks. As a rule, the nodules do not exceed three inches in diameter, but a few attain larger dimensions. In the raw condition the mineral is soft, light, and non-transparent. The color is white, with occasional blending of yellow, red, or gray. It is richer in silica than that found in Utah or North Carolina. The thickness of the meerschaum-bearing strata varies between 3 and 40 metres. Mining is carried on under the leasing system, both in open-cut and underground work. About 4000 men were employed in 1911. After extraction the product is sorted and cleaned. Six grades are prepared for export, mostly to Austria. The ore is shipped in boxes of a capacity of from 30 to 35 kg. of meerschaum. The following prices per box f.o.b. cars Eski-Cheir prevail at present according to grade, this classification being based entirely on the beauty and purity of the specimens:

Class.	Local Name.	Per box.
1	Sari Muli	\$160
2	Bir Nebrikli	135
3	Pamoukly	115
4	Dane Dukme	70
5	Orta Dukme	25
6	Giliz Dukme	10

A new deposit of coal was discovered at about three and one-half hours' ride from the city of Aintab. Samples seem to indicate that the coal is bituminous. The assay reveals rather high ash contents.

The oil district adjoining the Persian boundary, in the extreme southeastern section of the Empire, was the object of considerable attention during the year. The public press voiced the unanimous opinion of mining men in calling the attention of the Government to the necessity of undertaking a thorough investigation of the belt. No appropriations

could be devoted for this purpose, however, owing to the still precarious condition of Turkey's finances. An attempt was made by the Department of Mines to have the oilfield examined by the engineers of the more important railway companies. The matter is still pending, mainly because nothing short of a concession will be considered by a company undertaking such work, and there appears to be considerable reluctance on the part of the Government to grant any concessions until a better knowledge of the conditions prevailing throughout the oilfield enables the officials of the mining department to form an idea of the approximate value of what is suspected to be an important oil district. To judge from the satisfactory developments taking place on the Persian side, where an English syndicate is carrying on a systematic plan of development, it appears that it might be worth while to explore the Turkish field. A very small amount of the oil oozing above the soil, and which is collected on the surface of pits dug for the purpose, was gathered by the Arabs for their local needs all the way from Mossul to Bagdad and Bassorah.

No attempt was made, however, to transport the oil away from the immediate vicinity of the occurrence. The country's supply is derived from Russia, Rumania, the United States, and Austria. In many Turkish towns, as in Harput, for instance, petroleum sells as high as 30c. per gallon. All told, about \$5,000,000 worth of the oil was imported during the year. It therefore seems that there exists good reason for the endeavor to supply the 35,000,000 inhabitants of Turkey with the only means of illumination which will be available to them for many years to come. Attention is here called to the possibility of competing with foreign oils in the other markets of the East as well as those of the Far East. Aside from this, some of the most important Turkish railway companies finally decided, in the course of the year, to use oil as fuel in their locomotives. Trials which were made on the Anatolian railroads for the past two years have been so satisfactory that 100 locomotives are to be transformed. The Bagdad Railway Co. has also decided to adopt this fuel, and is about to build its storage tanks at Alexandretta.

The revision of the Turkish mining law was also undertaken during the year. The new provisions were to have been submitted to Parliamentary approval in the fall session of the year, but it appears that unexpected political events prevented their discussion by the legislative body, which found itself suddenly confronted by the necessity of attending to political matters of more immediate importance. It was not known at the time of writing (November 1911) whether the new law would be adopted before the end of the year or not. The changes proposed are believed to be of a nature tending to facilitate operations. In the main, the object sought was to have the Turkish mining law conform to the practice in vogue among the more advanced nations. The old text had been definitely promulgated in 1906 before the inauguration of the constitutional form of government and at a time when the country still labored under the mismanagement of its former ruler. As such, the various clauses of the law were framed so as to hamper as much as possible the free and natural development of the industry. Prospecting and exploration could be undertaken only by means of special permits, which were granted under conditions that were so restrictive as to be devoid of any practical value. These research permits, as they were called, were granted for a year and for small zones. Only the minerals specified in the permits could be sought, and a new permit had to be obtained for any ore that might be discovered and which was not specified in the document. Considerable 'pull' at headquarters was required for the issuance of these permits, and only a favored minority composed of Abdul Hamid's creatures could get them. Added to this, the Government taxes were abnormally high in some instances, and thus prohibited the undertaking of any work. The revision of 1911 has eliminated these obnoxious features, and while the final text of the new law will not be known until after Parliament has passed on the subject, there is no doubt of the fact that its provisions have been inspired by the same spirit

of enterprise which has characterized governmental action in the past two years. One of the results of this revision has already been felt in the increasing demand for mining concessions. It is believed that over 400 concessions will be granted by the end of the year, this number being about double the one granted formerly.

In the absence at this date of any precise figures for the year's mineral output, the following estimates compiled from data available so far, represent fairly accurately the year's production:

Antimony ore	metric tons	1,500
Asphalt	" "	12,000
Bituminous coal	" "	700,000
Boracite	" "	16,000
Chrome ore	" "	40,000
Copper	" "	1,500
Emery ore	" "	72,000
Gold	kilograms	45
Iron pyrite	metric tons	80,000
Lead	" "	13,000
Lignite	" "	35,000
Manganese ore	" "	18,000
Meerschaum	" "	250
Mercury	flasks	4,500
Silver	fine ounces	8,000
Zinc ore	metric tons	40,000

Nome in 1911

The report of R. W. J. Reed, Deputy Collector of Customs at Nome, Alaska, for the navigation season of 1911, gives an interesting insight into the business of this far northern community. The principal items are listed below:

Vessels from U. S. ports.....	36
Vessels from foreign ports	31
Passengers arrived from States at Nome.....	1,514
Passengers arrived from States at St. Michael....	778
General merchandise received, tons.....	21,685
Coal received, domestic, tons.....	1,650
Coal received, foreign, tons	6,010
Lumber received, feet, B. M.....	2,173,695
Live stock received, head	31
Sailings of vessels for U. S. ports.....	31
Sailings of vessels for foreign ports.....	36
Passengers outward, ocean vessels, from Nome....	1,998
Passengers outward, ocean vessels, from St. Michael	1,741
General merchandise shipped, tons	507
Gold-dust and bullion shipped:	

	Ounces.	Value.
Through Custom House....	142,013.44	\$2,612,219.12
Through postoffice	22,400.43	415,986.02
Totals	164,413.87	\$3,028,205.14

Since a census showed the population of Nome last winter to be 2602, and 484 more people left this season than came in, the present winter population may be taken at 2118. The coal received covers stocks at close of navigation.

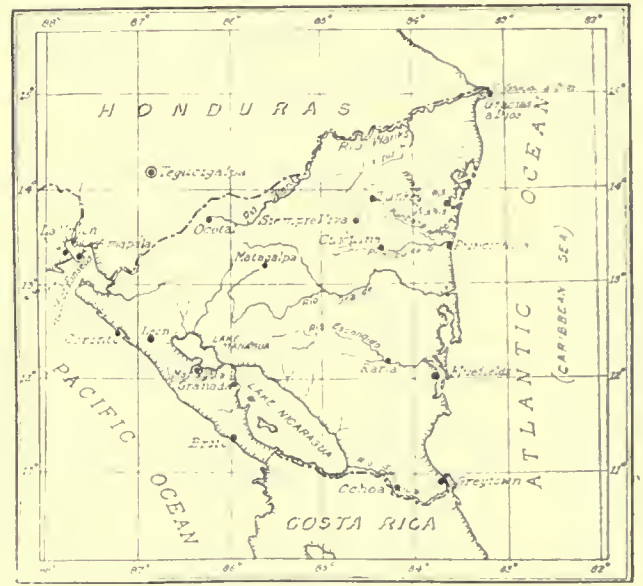

BORAX.—Virtually the entire product of borax in the United States is derived from two mines in California, one in Inyo and the other in Los Angeles county. The ore now mined is all colemanite. Marsh material no longer can be mined at profit, and the crude refining on the ground has given way to better work in large refineries. The industry is closely controlled. The output in 1910 was 42,357 tons, valued at \$1,201,842, according to figures collected for the U. S. Geological Survey by Charles G. Yale. This is about the average yearly production since 1903, except for the year 1907, when high prices stimulated mining, and 1908, when, following a drop in price, most of the smaller mines closed. About one-half the borax is consumed by the enameling industry in making kitchen and sanitary ware. New uses are constantly being found for the material and search is as steadily being made for new sources of supply.

Central American Mines in 1911

By T. LANE CARTER

Central America is generally considered to consist of the five republics, Guatemala, Honduras, Nicaragua, Costa Rica, and Salvador. Panama should be included in this list, but sometimes it is put in as South American. Mining in this part of the world has not yet come into its own. Unsettled and unsatisfactory political conditions, together with the lack of transportation, have been the principal causes for the backward state of development. The year 1911 shows some advance, and during this time the attention of capitalists has been more attracted to the mining possibilities of Central America than for many years past.

On account of the revolutionary troubles in Nicaragua and Honduras, the attention of the world was turned more to these two republics than to their more quiet neighbors. During 1911 Nicaragua settled down to comparative peace, after one of the worst revolutions in its history. Everyone recognizes the tremendous help that the United States ren-

NICARAGUAN MINING DISTRICTS.

dered to the revolutionary movement in an indirect way. Had it not been for this indirect help of the United States, ex-President Zelaya would still undoubtedly be in power. During the year, General Estrada, the leader of the revolutionists, was succeeded in the presidency by Adolpho Diaz, a distinguished citizen of the city of Bluefields. President Adolpho Diaz has been connected with mining in eastern Nicaragua for many years, having been employed by the La Lusa y Los Angeles Mining Co. As he is well acquainted with the needs of the mining industry, it is highly probable that he will do all in his power to advance the mining interests. During the year 1911 a fundamental weakness in the mining law of Nicaragua was brought to light. This cropped up over the negotiations for the Bonanza mine in the Piz-Piz district. This is in regard to the deep-level claims. Under the present law titles to deep-level claims are uncertain. Now that the weakness has been pointed out, there is no question but that the Government will change the law so that large companies going in there will be sure of their deep-level claims. One of the difficulties has been the existence of the Dietrich concession, which blankets a considerable district. No doubt this matter will be amicably adjusted in time.

At the beginning of 1911 there was a deal on for the Bonanza mine in the Piz-Piz district between the owner, Joseph La Pierre, and some influential capitalists in California. At first it looked as if the deal would go through, but there was a hitch somewhere, and about the middle of the year, after spending a considerable amount of

money in examination and development, the American capitalists decided not to go on. The failure of the sale seems to have been really acceptable to the owner of the Bonanza mine, and now that he is still to own the property, Mr. La Pierre has decided to put in new machinery and to work the mine on a larger scale. Negotiations are going on for the sale of the Lone Star mine, which is next to the Bonanza mine, and it is possible that this mine will be sold during 1912. The biggest mining deal during 1911 in Nicaragua was the purchase of the 18½% of the La Luz y Los Angeles mine for \$185,000 by the majority shareholders. This property is now entirely owned by some Pittsburg capitalists, and the price which they have given for the minority interest shows that they place a value of \$1,000,000 on this mine. The output of gold in Nicaragua in 1911 amounted to a little over \$1,000,000. At the present time this is the only metal of economic importance produced in this republic. It looks as if the mineral wealth of Nicaragua would prove to be principally gold.

Revolutionary troubles in Honduras were straightened out during the year. This republic groans under a terrific national debt of more than \$100,000,000. It is significant of the growing importance of Central America and the interest these republics are now exciting, that such a strong banking firm as J. P. Morgan & Co. is arranging to take over the debt, not only of Honduras, but to loan a large sum to Nicaragua as well. If the future of these republics seemed dubious, a firm as cautious as the one involved would never consider the lending of so much money. Recent revolutionary troubles have proved that the agreement entered into between the republics, not to war the one against the other, is to be strictly respected in the future. The United States will see to it that there is no more inter-republic strife. Whatever fighting is done in the future will be confined to internal revolutions in each republic. The outlook for permanent peace in Central America was greatly improved during 1911.

Mining in Honduras in 1911 did not make much progress. The premier mine of the country is, of course, the Rosario at San Juancito near Tegucigalpa, which has been in continuous operation for thirty years and has produced over \$16,000,000 in gold and silver. At present there is in sight about \$4,000,000. The milling plant is up to date and the mine is a dividend payer. There are other mines in the same district, and with better conditions they should develop rapidly. The Gigante, under development by San Francisco capitalists, has been under examination on behalf of English investors. Honduras seems to be rich in silver, but there have been recent denouncements in gold, lead, copper, kaolin, iron, marble, saltpeter, aluminum, chalk, coal, antimony, zinc, and nickel. While the figures are not yet completed for the production of 1911, the indications are that the gold and silver output for the year from Honduras will amount to nearly \$2,000,000, United States currency. A small amount of iron ore was also shipped.

Salvador is the most populous country of Central America, but as its people do not indulge in frequent revolutions, the world does not hear as much of this republic as Nicaragua and Honduras. During the year 1911 mining has been carried on successfully, the total product of gold and silver amounting to about \$1,300,000. It will be some time before the official figures are published, so this amount is only approximate. Conditions are more settled in this republic than in any of the others, and it has been more prospected than either Honduras or Nicaragua, two republics which in many sections are still unknown.

The Republic of Panama is known to the world more by its canal than as a mining country. Gold mining has been carried on in the Darien and Veraguas provinces for a long time. One company has closed its works on account of a defective cyanide plant having been built. The ore at this property is rather low grade, but with a suitable cyanide plant it could be made a success. The outlook for mining in Panama is fairly good. The country has not as much promise, however, as Nicaragua and Hon-

duras seem at present to hold out.

Costa Rica has developed more in agriculture and fruit-growing than in mining. There are one or two properties, however, owned by close corporations of American capitalists, that are making good profit. As far as stability of government is concerned, Costa Rica is the most fortunate of the Central American republics, and during 1911 there were no political disturbances. The effect of the serious earthquake in 1910 was still felt during 1911, and mining did not make any marked advance.

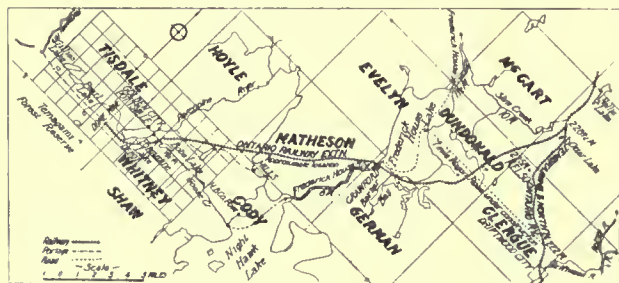

Mining in Guatemala is at a low ebb, not because the country is without mineral resources, but on account of unfortunate conditions, principally the lack of transportation. The small amount of gold now being produced in the republic comes from placer mines. Some prospecting was done during the year, and Guatemala is now known to contain deposits of gold, silver, copper, iron, lead, zinc, and antimony. An interesting deposit of mica not far from Guatemala City was brought to my attention recently. Not sufficient is yet known of this deposit to tell what its value will be. A most interesting and promising district in Guatemala attracted some attention during the year, namely, Alotepeque, about 65 miles south of Puerto Barrios in the eastern part of the republic. A map of the region will show that this district is near the corner where the three republics, Salvador, Guatemala, and Honduras, join. In the Middle Ages a considerable amount of mining was done here, and there is an old silver mine with a great record as a producer of white metal. Some years ago the Venture Corporation of London had an option on these properties, but never took over the mines. The indications for the opening up of a large amount of zinc, lead, and silver ore are most favorable, and during the year 1911 there were several inquiries on the part of big owners regarding these mines. The railroad people in Guatemala have intimated that they will build into this district whenever they see a crowd of financiers big enough and earnest enough to make a success of the venture. This district of Alotepeque is one of the most attractive in Guatemala. Being so near the railroad, the ore can readily be shipped to the smelters of Europe, and no doubt in time this district will contribute a great deal of lead-silver and zinc ore to Germany and Belgium. The freight from the mine to Hamburg will be remarkably low, and if these prospects develop as they promise, ore from this district will be able to compete with almost any for the European trade. It is probable that during the next year or so there will be considerable development in this part of Guatemala.

Mining in Central America is dependent to a large extent on railroad development. There has been progress made during 1911 in this direction. The proposed railroad from Bluefields, Nicaragua, by way of Rama to the lake will probably aid agriculture as much if not more than mining. Those best acquainted with the mining resources of Nicaragua would have preferred to have a railroad into the Piz-Piz district, as this region is the most promising of the gold areas of Nicaragua. The proposed line will serve one old mining district, at any rate, namely, the Libertad district in Chontales, where gold has been mined for over sixty years. In Honduras it is proposed to connect the capital, Tegucigalpa, with the coast by means of a railroad. The construction of this road will greatly stimulate mining in Honduras. It will not be many years now before the traveler can go by rail from New York City through Mexico, Guatemala, and the other republics to the Panama Canal. This line will mean as much to the people of Central America as the Cape-to-Cairo line means to Africa.

It is a satisfaction to state that during 1911 real progress has been made in Nicaragua in the improvement of the gold metallurgy of the country. At the Siempre Viva mine, the manager, H. B. Kaeding, has attacked the slime question with energy and ability, and it looks as if under his guidance this property will become a dividend payer, as it promised to become when first examined by Courtenay De Kalb about twenty years ago.

Mining in Eastern Canada in 1911

The year just closed has been characterized by marked progress in the mining industry, more especially in the Porcupine district. The rapid development of this field has been largely due to the extension of the Temiskaming & Northern Ontario railway, owned and operated by the Ontario Government, to Porcupine Lake, previous to which great difficulties were experienced in transporting heavy machinery and supplies. In the month of July the surrounding country was ravaged by extensive bush fires, which swept the camp, causing great loss of life and destroying or seriously damaging the buildings and plant on most of the mining properties. This disaster considerably delayed production, but the work of reconstruction was begun as soon as possible and actively carried on throughout the fall, with the result that the hastily erected temporary structures of the early days have generally been replaced by permanent and substantial buildings suited for operations on a larger scale. Prospecting has also been rendered easier by the clearing up of the country by the fire, and many important discoveries have been made. Underground work and diamond-drilling have also proved several of the mines at depth, assuring the occurrence of sufficient milling ore to justify the erection of stamp-mills. The actual production of gold has as yet been small, but

RAILWAY TO PORCUPINE.

considerable quantities of ore have been accumulated in readiness for the machinery, and it is announced that the mills of the Dome, the Hollinger, and the Vipond will be in active operation early in the year. During 1911 the known gold-bearing area of the district has been considerably extended by discoveries in outlying areas, including Swastika, West Shining Tree, and Bristol township, the most promising of these being the Swastika, where development on an extensive scale has been undertaken on several properties. Porcupine has attracted widespread attention from both American and British investors, and much capital has been drawn from these sources. The principal drawback, however, has been the extravagant prices placed by the owners upon improved prospects, which has done much to retard development.

There has been a considerable revival of interest in the gold-mining districts of northwestern Ontario, more especially the Lake of the Woods and Manitou Lake areas, where several mines which were formerly producers have been reopened, after having been closed for many years. Some of them had ceased to be remunerative owing to the antiquated methods then in vogue of mining and ore treatment; but it is anticipated that with the use of modern machinery and the latest processes, they can be profitably operated.

While the silver-mining industry at Cobalt has made steady progress, the leading mines continuing to yield fair returns upon their capital, this field has been eclipsed in public interest by the greater prestige of Porcupine. The industry suffered during the winter and early spring from a shortage of electric power, but when this difficulty was overcome by the return of open weather, normal conditions were resumed and the output of silver showed a satisfactory increase as compared with the previous year. The most noteworthy feature was the extensive substitution of concentrating and refining processes for the shipment

of low-grade ore, resulting in a steady diminution of the tonnage output. Statistics for the nine months ended with September show that while the ore shipments, as compared with the corresponding period of 1910, have decreased from 23,824 to 18,592 tons, the quantity of concentrate sent out has increased from 4633 tons to 6915 tons, and the output of bullion has risen in value from \$247,263 to \$1,116,571. The Nipissing company has for some time been successfully treating its high-grade ores by a combined system of amalgamation and cyanidation, and has arranged for the erection of a 200-ton plant, in which the low-grade output will be treated by a modification of the same process, which will largely increase the value of its ore reserves. The same company has erected a hydraulic pump for the purpose of removing the overburden on its property, in the hope of discovering new veins. During the later months of the year the La Rose Consolidated materially improved its position by important discoveries on several of its properties. The company continued the conservative policy of accumulating a large reserve fund instead of increasing the rate of dividend. While the prominent mines have generally maintained their shipments, the stock market for some months previous to the close of the year showed great depression, and a number of the weaker issues entirely disappeared from the list. The outlying districts of the Cobalt field contributed comparatively little to the silver output, the figures for the first nine months of the year being: Cobalt, 22,272,783 oz.; South Lorraine, 626,131 oz.; Gowganda, 286,925 ounces.

The earlier part of the season witnessed increased activity in the production of iron ore and pig iron. The slackness of the iron and steel industries in the United States, however, seriously affected conditions in Canada, and some months since several of the iron ore mines in Ontario and Nova Scotia were closed for the season. Production has been actively carried on, however, at the Helena mine in the Michipicoten district of Ontario, with an output of about 1100 tons per day, most of which is consumed in the furnaces of the Algoma Steel Works at Sault Ste. Marie, and other mines in that district have been active. The iron-manufacturing industry was adversely affected by the withdrawal of the bounties on iron and steel, given for some years by the Canadian Government, and a movement for their restoration has been set on foot. Meanwhile, the manufacturers have been endeavoring to meet the change of conditions by effecting greater economy in production. Important extensions have been made to the plant of the Dominion Steel Corporation, at Sydney, N. S., which will largely increase the output, and the Steel Company of Canada is preparing to make additions to its plant at Hamilton, Ont., at a cost of \$2,000,000, including a rod, blooming, and billet mills, and two 60-ton continuous open-hearth furnaces.

The coal output of Nova Scotia has considerably increased. The Dominion Coal Co. is increasing the number of its collieries from four to twenty, and has broken all records for production during the season from May to November, its output amounting to 2,480,000 tons, as against 2,363,970 tons in 1910. Of this quantity 1,501,000 tons was shipped to the St. Lawrence ports, the total coal shipments from Nova Scotia to that market aggregating nearly two million tons.

Production has been steadily carried on in the nickel-copper mines of the Sudbury district, though the latest available returns show a comparatively slight diminution in the output as compared with 1910. The asbestos industry in Quebec province is at present under a cloud, owing to the failure of Amalgamated Asbestos, Ltd., a merger embracing many of the leading mines, to meet the interest on its bonds for \$8,000,000, by reason of the depressed condition of the asbestos market. A financial reorganization will be necessary. Mica mining was slack during the greater portion of the year, many properties in Quebec and eastern Ontario being closed down with accumulated stocks on hand on account of the low prices prevailing. Recently, the market has improved and the prospects for the industry are favorable.

Transvaal Gold-Mining

By ROWLAND GASCOYNE

GENERAL CONDITIONS

The year in South Africa, despite the chronic shortage of native labor, was marked by steady progress in many important particulars, of which there is room to mention but a few. Extensive drilling under expert guidance seems to have finally dissipated any large hopes of discovering new areas of gold-bearing banket comparable to the Rand, or any considerable extension of the present known area. In this, and in other particulars, the Rand is settling down into the period in which the best possible use must be made of known resources and less expectation based upon the unknown. Outside the Rand there have been no important gold discoveries, and in the Barberton and Lydenburg districts 1911 has brought little change. The year has chronicled the entrance of the Randfontein Estates into the struggle for the position of the largest gold producer on the Rand and in the world, but while the company has on several occasions beaten the East Rand Proprietary Mines, it was not until October that it succeeded in passing the Crown Mines and taking the top position on the list. The entrance of the Bantjes mine into the producing list has been an important feature of the year, but for some reason or other, the results have not come up to expectation. Another interesting new producer was the City Deep, and there have been numerous other changes in rank among producers. The metallurgical record is one of much interest, and is briefly sketched elsewhere by Alfred James; the share market is discussed by T. A. Rickard; these pages will be devoted, therefore, to improvements in mining technology.

RECTANGULAR Versus CIRCULAR SHAFTS

During the year the amount of vertical shaft-sinking carried on has been below the average. The starting of the four large rectangular shafts on the goldfield known as the Government Areas without any previous boring to prove the position of the Main Reef series caused some comments in mining circles, especially in such a variable area as that of the Far East Rand. When, however, it is recognized that this huge field has been practically proved on all sides by neighbors such as the different Modderfontein properties, Van Ryn Deep, Brakpan Mines, and Geduld, there does not appear to be much necessity for preliminary bore-holes. Drilling in the same neighborhood has shown that bore-holes are valueless as indicators of the probable average yield of a deep-level goldfield. At Geduld they gave excessive assay values, and at Brakpan much less than actual mining operations have shown. As indicators of the strata to be passed through and the depth of the reef, bore-holes are undoubtedly valuable, but practically all this information was, in this case, available. This is another instance of the closer relation deep-level mining on the Rand now bears to coal rather than metalliferous mining. Sinking of circular shafts on the Rand has also emphasized the relation. This is not by any means the first time a circular shaft has been sunk on the Rand; in fact, there are several circular shafts in existence already at Rand gold mines. Nor does it indicate that all the shafts in the future are likely to be circular. Shaft shape on the Rand will probably be more governed in the future by the surrounding conditions than has been the case in the immediate past. The advantages and disadvantages of both circular and rectangular shafts have been largely discussed on the Rand during the past year. Late in the year the Welgedacht Exploration Co. was compelled to cease sinking a rectangular shaft owing to the excessive water, which was officially stated to be less than 2,000,000 gal. per 24 hours. In twelve months the shaft had been sunk only about 200 yards, at the somewhat excessive cost of £170 per yard. At the Grootvlei mine, only a few hundred yards away,

a similar monument to the difficulty experienced in sinking a vertical rectangular shaft through heavily watered strata is to be seen. In both instances, before sinking operations were commenced, it was anticipated that large bodies of water would be met. It is well known and recognized that a circular-shaped shaft can better deal with large bodies of water than one of rectangular shape, and that quantities up to 10,000,000 gal. per day have been handled with comparative ease, but here are instances of rectangular shafts disabled and stopped after the expenditure of double the amount probably required to sink and line a circular shaft. Then, too, in these deep-level vertical shafts designed to work enormous areas, the ventilating advantages are all with the circular shaft, and ventilating difficulties are coming to be recognized on the deep-level properties on the Rand. It is principally on these two grounds that the reappearance of circular shafts during the year is to be welcomed, but their introduction is naturally meeting with some opposition from engineers who have always used rectangular shafts. No one will

SOUTH AFRICA.

deny the many advantages a rectangular shaft possesses where the ground is strong, a moderate amount of water is made, and the property is small and of uncertain value, but the experience on the Rand during the last twelve months seems to indicate that where the Witwatersrand beds are overlain by a considerable thickness of soft ground and dolomite carrying heavy flows of water, circular-shaped shafts may be necessary, while for ventilation purposes in some of the deep and extensive mines, they may even become indispensable. A somewhat premature start was made on the West Rand Estates to sink a circular shaft through bad and wet ground, but owing to difficulties with the special pumps designed for the purpose and insufficiency of capital, work was suspended after reaching a depth of only 20 ft. At the Government Area mines on the Far East Rand, where four large deep shafts are being sunk to the Main Reef series, the question of the shape of the shafts seems to have been fully investigated, and, after all the advantages and disadvantages of both circular and rectangular shafts were considered, it was decided to continue the almost general Rand practice of sinking rectangular shafts. These are now making rapid progress.

VENTILATION AND HEALTH

During the year a goodly number of ventilating fans have been installed at several of the older mines and, owing to the air having to pass through rectangular shafts of small dimensions, it has been found necessary in some cases, owing to the excessive resistances offered to air currents in these rectangular shafts, to place the fan underground. Underground ventilation has, indeed, attracted much attention this year. Some time ago a system of fan ventilation was introduced at the East Rand Proprietary mines with such satisfactory results that quite a number

of fans were installed during the year just closing, the Sirocco type perhaps being the greatest favorite. It has been found on the Rand that where operations reached a depth of 3000 ft., natural ventilation aided by compressed air is insufficient to keep the mines in a healthy condition, or meet the requirements of the mining regulations. According to Section VI of the Transvaal Mining Regulations, not less than 70 cu. ft. of air must be provided for each person employed below ground, a requirement not always insisted upon in the past, and one, moreover, that natural ventilation cannot, under all circumstances, be expected to supply. Owing, probably, to more attention being bestowed on ventilation, there have been apparently fewer 'gassing' fatalities than usual during the year. If the provisions of the mining regulations were carried out, especially those providing that all working places and traveling roads shall be in a fit state for persons to work and travel therein, these 'gassing' fatalities would altogether disappear. There seems to be a stronger tendency to carry out the mining regulations since the responsibility for complying with them was placed on the shoulders of the mine managers, but there is still room for improvement. In the Transvaal no inquests are held and no particular attention is called to mine accidents, although they are published monthly by the Government Mining Engineer. Up to the time of writing, no unusual accident of any magnitude as regards loss of life has occurred during the year.

MINE DUST AND MINERS' PHTHISIS

During the current twelve months miners' phthisis has attracted unusual attention, especially in the Union Parliament, where an ill-considered and somewhat premature measure on the subject was introduced and afterward withdrawn. Legislation has been postponed until further knowledge is available. It was known, however, that the disease had secured a good hold on the mining population, one official of the Mines Department and a mining expert fixing the proportion at one in four of the underground miners, but this is probably an exaggeration. So many cases are known to exist that the Government felt compelled to pass a scheme of relief for advanced cases to which the Government as well as the mining companies were called upon to subscribe. The fine Rand quartzite dust is perhaps the most prone to cause miners' phthisis of any known mine dust in the world, and what seems equally striking is the fact that the miners on the Rand are the most careless and negligent of any in taking effective steps to guard them against the disease, even if every appliance is supplied them for that purpose. According to the mining regulations, every dry development place and dusty stope must be provided with a continuous adequate supply of water for damping the broken ground and allaying the dust caused by drilling operations. No persons are allowed to drill holes unless a water jet or spray or other device is provided so as to prevent the escape of dust into the air or to remove broken ground before it has been effectively damped. The complaints that miners neglect to take any precautions to prevent the spread of the disease, particularly with regard to the use of water, are all the more remarkable, seeing that by its use drilling operations underground are considerably facilitated. So striking is this neglect on the part of the miners that a paper on the application of water to underground drilling operations and the advantages accruing therefrom at the Nourse Mines, was read by one of the assistant mine inspectors. It led to an interesting discussion in which frequent mention was made of the aversion of the miners underground to the use of water as provided for in the regulations. Even at the Nourse Mines it was stated that the system had not been introduced without considerable coercion on the part of the management.

CONCENTRATION OF UNDERGROUND WORK

The most important step taken during the year with regard to actual underground operations on the Rand appears to be that of concentrating as much as possible of the work. In the past, when the areas worked by the

same company were smaller than they are today, the vagaries of the yield and the higher costs did not allow this to be done, and the higher average yield also allowed operations to be scattered in order to secure the highest regular monthly yields, because at that time working costs were not considered of such primary importance. Today the amalgamated concerns on the Rand face a different aspect, each mining large areas where the yield varies considerably in value. Some of these amalgamated concerns are operating at enormous depths, and it is becoming necessary to adopt a systematic method of working, which in itself means concentration, and it is hoped a much lower average working cost per ton. Briefly, it has been decided, in order to facilitate deep mining, to adopt stage winding, and on all the large properties, main levels of large dimensions are being driven as straight as possible from one end of the properties to the other, the first at depths not exceeding 3000 ft. These main levels are intended to act as feeders to the shafts, and outputs carrying up to 6000 tons per day of 10 hours from one shaft are expected. These are supplied with ore from above as well as below by subordinate levels, as much as 300 to 500 ft., according to the dip of the reef and other conditions. These principal levels will also be fitted with electrical or mechanical haulage, as may also be the subordinate levels where conditions are favorable, so that underground tramming expenses ought to be reduced to at least one-half of their present figure. Similar main levels will be driven as greater depths are attained, the second stage of winding being thus fixed at something less than a depth of 6000 ft. This, however, is at present all anticipation, as the deepest workings have not as yet exceeded 5000 ft. Another proposal is to work the reefs on the Far East Rand, where they run fairly flat on a modified system of longwall; the most recent proposal being to construct the principal drives in the foot-wall and at considerable distances apart. It was several years ago that the longwall method of working was first suggested for the flat reefs at Geduld in the Far East Rand, but it has never been adopted. More recently a modified system of longwall has been suggested for some of the neighboring properties. In both these methods of working, operations underground will be closely concentrated, and the ore removed at one operation. Under these circumstances, the cost of mining per ton ought to be materially reduced. Whether these systems of working the Rand reefs will be sufficiently cheap to withstand the effects of varying yields or the desire for uniform monthly results, and at the same time compensate for the variation in ore values by a large reduction in the working costs, remains to be seen.

DECLINE OF GRADE AND COSTS

During the year the question of a gradual impoverishment of grade with depth on the Rand has been much discussed, one mechanical engineer putting forward the view that at an average depth of 4000 ft. the grade would have fallen and the working costs increased to such an extent as to render further mining unprofitable. There is, however, nothing to show that the Rand will suffer as much general depreciation in depth as other mining fields in the world, while the idea that working costs must necessarily increase with depth is most distinctly opposed to what has actually occurred during the past twenty years on the Rand. There are numerous instances on the Rand where the grade has fallen with depth, and it may continue to fall for some time to come, but there are also other instances where after declining it has recovered. In almost every instance, working costs have declined with depth; perhaps not so much on the average as the grade milled, but it is becoming palpably clear that while a mining engineer cannot introduce a higher yield, he can and does bring about lower working costs when same are absolutely needed. In other words, he can adapt himself to surrounding conditions, and nothing seems more calculated to reduce the working costs on the Rand than the stern necessity which will be created by a lowering grade. On this and general grounds, the attempt to limit profitable mining on the Rand to a depth of 4000 ft. must therefore

be regarded as quite unjustified by the short history of the Rand.

SAND FILLING STOPES

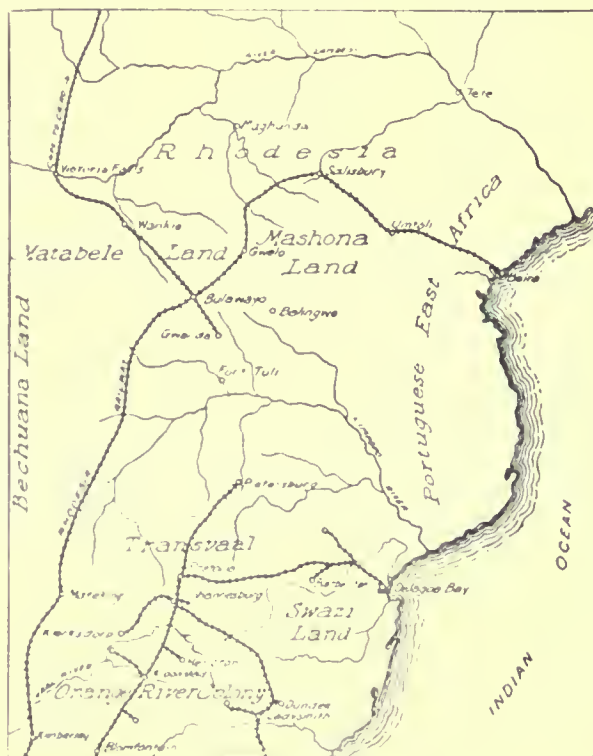

The practice of sand-filling the exhausted stopes is gradually being extended, but it is far from being generally used. In no case, however, where it has once been started, has the practice been abandoned. To support buildings and shafts where careless mining has caused a movement, sand-filling has proved an unqualified success. It is found that a vertical 4-in. pipe can convey 400 tons of sand per hour quite easily in a mixture of 3 tons of sand to 1 ton of water. One ton of water to 4 tons of sand may be used in most cases, but with well arranged launders and bins on the surface, 1 ton of water to 5 of sand may be used. Special bore-holes for conveying sand to the stopes have been made, one at the Robinson Deep extending over 1600 ft. deep from the surface. If lime is used, it is found that ordinary bare pipes or porcelain-lined pipes are best; wood-lined pipes have been abandoned. For straight inclined runs, wooden launders are the best. The Rand tailing is very destructive to pipes, and their cost, including renewals, runs from $3\frac{1}{4}$ d. to a penny per ton of sand delivered into the stopes. The wooden barricades necessary to retain the sand in position along the levels until drained and set, are the cause of great trouble and also largely contribute to the cost, which might be avoided if mining operations were conducted in the first instance with a view to sand-filling. The total cost of sand-filling varies considerably. Where things are well arranged at the surface and conditions favorable, it may be as low as 3d. per ton of sand filled. Generally, however, it costs about 6d. per ton, and in one case where the surface arrangements are anything but good, it costs 10d. per ton. Even at this high cost, in this particular instance it pays for itself, and the impression is gaining ground that if primary mining operations were conducted with a view to subsequent sand-filling, and so the leaving of pillars rendered unnecessary, a direct profit rather than additional cost would result.

ELECTRIC POWER

Perhaps the most important feature of the year has been the success attending the general application of electrical power to mining operations. For pumping, surface haulage, and lighting purposes, electricity has been in use for many years, but during the year it has been successfully applied to milling, hoisting, air-compressing, underground haulage, and all the hundred and one processes on the mines needing the application of power. Today there are few mines where electrical power is not in use, and had the Victoria Falls & Transvaal Power Co. been in a position to meet the demand, or even to carry out its contracts, the use of electrical power on the Rand would have been far more general than it is today. Many of the mills on the Rand during the year have been changed over from steam to electricity, and when the power supply has been ample and uniform, the millmen prefer using electrical power to steam. Electrical hoisting has also come much into vogue on the Rand during the year. The Eckstein group of mines has adopted the three-phase system, while in the majority of other cases the Ward-Leonard system has been chosen. There is considerable discussion going on at present, with regard to the different merits of the two systems. The three-phase system is the cheaper in first cost, and for slow hoisting and shallow depths has many advantages over the Ward-Leonard system. Its principal drawback is that its control is less perfect and reliable than the Ward-Leonard system. On this account, where the shaft is deep, loads heavy, and speed anything approaching or exceedingly 2000 ft. per minute, the Ward-Leonard system is generally preferred. The advocates of this system point out that, although its first cost is greater, there is not much difference when running costs are taken into consideration. At no time and under no consideration, they urge, should general safety of life and limb and better control be sacrificed, even to save capital expenditure.

Rhodesian Mining Development

The unskilled labor problem in Rhodesia is as acute as ever, and mining concerns, individual workers, and farmers throughout the country are putting their heads together and endeavoring to discover new ways and means of augmenting the labor supply. With a view to improving the situation, the Labor Bureau has been reorganized, and the new concern has a capital of £75,000 in debentures bearing 5% interest. The new Bureau proposes spending a considerable amount in establishing new rest depots and routes, and in exploitation of areas which have not as yet been visited by labor-recruiting agents. Meantime, work at the various mines progresses, even if not at the most desirable speed. Developments at the Shamva mine in the Abercorn district of Mashonaland continues satisfactorily, and there are now about 1,600,000 tons of ore developed, the average assay value being in the neighborhood of $4\frac{3}{4}$ dwt. per ton. Provision for a railway has been

RHODESIA.

arranged and plans for the equipment of the mine and battery are therefore being prepared. The Kansanshi copper mine, which is situated on the Congo-Rhodesian border, has delivered close on 500 tons of copper to the Northern Extensions railway. The Kafue Copper Co. is also conducting productive operations. The smelter of this latter concern was worked for 23 days during September and produced 327 tons, 73.5% matte. The British South Africa Co. has announced the flotation of a mines development company with a capital of £250,000, which has been hailed with satisfaction throughout Rhodesia. The avowed objects of this flotation are (a) assisting to bring about the more rapid development of mining in Rhodesia, (b) consideration of prospecting schemes, and (c) formation of subsidiary companies. It is hoped that this will lead to more rapid development of the country. Another Rhodesian flotation of importance is the Planet-Aretnus Gold Mines, Ltd., which possesses a capital of £475,000 in £1 shares. Of this sum, £150,000 has been set aside for working capital, and shares to this amount will be offered at par to shareholders in the Rhodesia Exploration & Development Co., of which Planet-Aretnus is a subsidiary. The properties to be acquired by the new company are situated in the Enterprise district of Mashonaland, and at no great distance from what are known as the Gold Schists of Rhodesia Mines.

Gold-Dredging in Russia

By CHARLES JANIN

*Statistics of the dredging industry in Russia and Siberia have been collected yearly since 1906, by the permanent consulting board of the Gold and Platinum Producers Association. Translations of the published reports in *Zoloto i Platina* appear, from time to time, in the technical press, and show that the dredging industry plays an important part in Russian mining. The number of dredges in Russia has increased steadily from 40 in 1906, to 66 in 1910, and a number of new ones are reported for 1911.

DREDGES OPERATING IN RUSSIA, 1906-1910

	No. of dredges in existence ...	Dredges reporting	Average No. of working days..	Average hours worked	Cu. yd. handled per dredge	Approximate recovery per dredge	Approx. value per cu. yd.....
1906	40	32	173	2837	159,600	\$19,205	12.0
1907	64	46	137	2259	139,300	20,235	14.5
1908	64	49	149	2502	166,400	25,380	15.2
1909	64	41	164	2771	188,805	32,185	17.9
1910	66	55	...	2914	182,486	31,357	16.0

Dredges, with buckets of 4½ to 5-cu. ft. capacity, predominate, though there were 22 having 7-ft. buckets, in 1909, and many of the newer ones are of this size. The average yardage handled per dredge in 1910, for 55 dredges reporting, was 182,486, on an average working time of 2914 hours. This gives 62.6 cu. yd. per dredge per hour, which is small, compared to the 500 yd. per hour sometimes reached by the modern 15-ft. California boats. Dredging, in Russia, seems particularly characterized by the small percentage of dredges that are reported as working at a profit. Though the average value of the ground worked in 1909 was 17c. per cubic yard, only 25% of the dredges operating that year made a profit, and, according to a translation by W. H. Shockley, in the *Mining and Scientific Press* of May 20, 1911, "if attention is given to the royalty paid, several dredges must be excluded from that list." According to the data furnished by the commission, in order to pay the operating expenses of a dredge, allowing for amortization, it is necessary to work ground of the following value, the figures being in cents per cubic yard:

Bucket capacity, cu. ft.	Urals.	Western Siberia.	Eastern Siberia.
2	22.96	28.04	32.72
4	15.15	17.96	20.40
5	12.18	14.35	16.24
6	10.59	12.62	14.14
7	9.55	11.56	12.98

According to S. I. Littauer, 46 of the dredges operating in 1909 dug material exceeding the gold content indicated as necessary for commercial success, yet many of the dredges actually worked at a loss. In the report for 1910, in many cases the names of the dredge builders are given, and, while the list is not complete, it is interesting to note that out of 36 dredges, 7 are of foreign make. It is admitted that the Russian-built dredge cannot compare in material used, construction, and efficiency with the foreign-built boats, especially those of American manufacture, and there has been considerable agitation among those interested in the Russian gold placers to have the duty again taken off gold-mining machinery. For a period of ten years, this duty was remitted, but a few years ago the Government, acting in the interests of the dredge builders, put the duty on again, though the free importation of machinery is, I understand, still permitted in the Amur and Premorsk districts in Eastern Siberia. The dredges built by the Russian build-

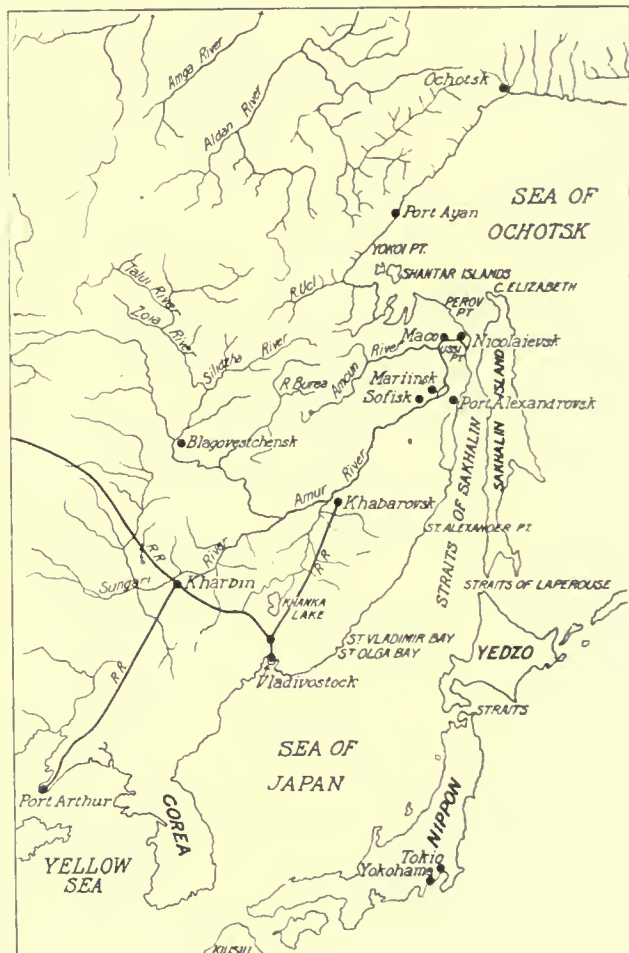

ers are of lighter construction, and made of material much inferior to that used in dredges following the best American practice. An instance of lighter construction in the case of steel hulls may be mentioned. According to Ross B. Hoffmann, the hull of a 7-ft. Russian-built dredge weighed 190 tons; this is only about one-half the weight of the steel hull on the American-built Kolehian dredge, described below.

Among the new installations for Russia, in 1911, are two Werf Conrad dredges in the Amgun district, Siberia. One

FORWARD VIEW OF STEEL HULL, KOLCHAN DREDGE, SHOWING ROUNDED BILGES.

of these has buckets of 7-cu. ft. capacity and is designed for a working depth of 25 ft. The total engine power is 160, and the dredge hull is of steel. The other dredge is a small prospecting machine, with a bucket capacity of ½ cu. ft., and is said to be driven by hand-power. The Kolehian dredge, of the Orsk Goldfields, Ltd., was put in com-

MAP OF EASTERN SIBERIA. THE KOLCHAN MINES ARE A SHORT DISTANCE NORTH OF NICOLAIEVSK.

mission October 25, of this year. This is an installation that has attracted wide attention among those interested in the Siberian dredging industry. The ground was prospected by C. W. Purington and J. Power Hutchins, with Empire hand-drills, and a stacker scow, was put in operation on the property in August 1909. This was described by Mr. Purington, in the *Mining and Scientific Press*, February 4 and

*Reviews of gold-dredging in other countries will appear in a later issue.

11, 1911, and was also mentioned in my article in the number of October 14. Figures of operation for the entire past season are not available, but for the greater part of the season the plant has been averaging about 1000 yd. per day, and has produced during the past five months, \$121,000, gross. The total operating cost, exclusive of administration, amounted to \$16,650. The difficulty of disposing of the tailing, the cause of many failures on plants of this character, was overcome by mounting the machinery for washing and stacking the gravel on a scow and floating it behind the excavating machine. The washing apparatus was specially arranged to meet the conditions, the gravel containing much clay. The plant was designed and built by the New York Engineering Co., which also designed and built the Kolchan dredge.

The Kolchan dredge has buckets of 8-cu. ft. capacity and a steel hull 95 by 40 by 9 ft., weighing 375 tons. The dimensions of the hull are as follows. It is 95 ft. long, 42 ft. beam, and 9 ft. deep. Frames are spaced 28 in. apart,

industry in Russia. The Russian capitalist is well known for his timidity in entering unknown fields in the development of a new industry and it will be due to the initiative taken by American and English capitalists, that any great advance will be made in gold-dredging in Russia. The field should be particularly attractive to American investors. The gravel is rich, the climate and physical conditions somewhat similar to Alaska. While the low operating cost obtained by the California dredges are for various reasons impossible in Russia, the introduction of the modern California type dredge will unquestionably show that thousands of acres of auriferous gravels that are at present considered unprofitable, or that are not yet exploited, can be worked at a profit. Mining engineers, familiar with the conditions, and dredge builders in general, are devoting attention to the dredging possibilities in Siberia. The success of the Kolchan dredge, which, so far as I know, is the first modern American type boat in Siberia, will undoubtedly encourage the investigation of new areas, in the interests of American

KOLCHAN DREDGE, EASTERN SIBERIA, BUILT BY NEW YORK ENGINEERING COMPANY.

with 10-in. floor beams, and 6-in. deck beams. These beams consist of what is commonly known as ship-channels. Two solid bulkheads of $\frac{1}{2}$ -in. steel plate, reinforced by 4-in. angles run throughout the entire length of the dredge and form each side of the well. Cross bulkheads of solid plate extend across the pontoons at the different points, and the hull really has a double stern. The last frame, placed 28 in. from the stern, is built up of solid plate so that a separate compartment is formed at the rear of the dredge, and in case the spuds break through the shell at any time, this affords ample protection. The hull weighed about 350 tons, which is about twice as heavy as the same size hulls that are now in the course of construction by some others. A 500-hp. steam-plant generates electric power. This plant consists of a cross-compound, medium-speed, 4-valve engine, directly connected with a 400-kw. generator wound for 6600 volts, 3-phase alternating current. The power is transmitted ten miles to the dredge, where it is stepped down to 440 volts. A complete machine-shop equipment, a wood-sawing and splitting plant, together with two 700-ft. conveyors for stacking and conveying the fuel to the boiler, a complete pneumatic riveting plant, besides dredge extras and traction engines for hauling material, were included in the plant equipment, and the complete plant, weighing 2000 tons, was built to design and shipped in four months and ten days; a noteworthy record.

The number of dredges working in Russia seems small in comparison with the vast placer areas in that country, and may be partly attributed to the high operating cost, and inefficiency in general, of the Russian dredge, which would tend to discourage further installations; also to the lack of capital, which is perhaps the most important circumstance retarding the development of the dredging in-

and English capital. To those interests, when associated with influential Russians, and under the direction of competent engineers, Siberia offers, in my opinion, one of the most attractive fields for the mining capitalist.

Diamond Mining in Africa

There is not much new regarding African diamond mines. No new profitable mines appear to have been discovered during the year, but better prices have ruled, and the large producing mines at Kimberley and Pretoria have done better. The Premier mine near Pretoria is the only mine of any importance in the Transvaal. The output shows but little change, the improvement in price for the stones has, however, benefited the company, but the Government impost of 60% of the profits is one the company finds burdensome. Attempts have been made during the year to revive interest in several abandoned diamond areas in the Pretoria district, but without success. The Montrose diamond property continues to be worked at considerable loss to the shareholders, with little prospect of any change for the better taking place, and why work should be continued on this property under the circumstances is difficult to understand. In the Free State diamond fields the year has brought no important change, even the alleged discovery of the new pipe at Roberts Victor mine has turned out disappointing. At Voorspoed mine no change can be noted, the Crown diamond mine continues closed, but the old Monastery mine has changed hands during the year and operations on a small scale are being started. Altogether the year has been a better one for the diamond-mining industry than the preceding one and closes with encouraging prospects.

Metal Mining in British Columbia

By E. JACOBS

Viewed from the standpoint of production only, the year 1911 was not a good one for mining in British Columbia, but speaking generally, satisfactory progress was made.

Cariboo and Cassiar.—Barkerville district and Quesnel division, Cariboo, and Atlin division, Cassiar, are the two important placer-gold producers of British Columbia. Both report a decreased production in 1911 as compared with 1910—about \$460,000 from the two districts, as compared with \$522,000 in 1910. A shorter season for gravel-washing is the reason for the decrease; the season opened late, and there were no fall rains to help out. In both districts there are large beds of gravel available for hydraulicking. A feature in Cariboo was the commencement last summer of operations by the Quesnelle Hydraulic Gold Mining Co., which under the direction of Howard W. Dubois, of Philadelphia, expended nearly \$1,000,000 in preliminary work and equipment, and the resumption of work near Quesnel

MINERAL DISTRICTS OF BRITISH COLUMBIA.

Forks by John B. Hobson, the veteran hydraulic placer miner of Quesnel division.

East Kootenay.—Metal mining did not make much progress during the year. Exhaustion of the known orebodies of the St. Eugene lead mine, from which an aggregate of about 1,100,000 tons of ore has been taken, is near at hand, the production of concentrate having decreased yearly from 28,000 tons in 1905 to less than 6000 tons in 1911. The Sullivan has in part taken the place of the St. Eugene, but its enormous ore reserves contain much ore in which the percentage of zinc is too large to allow of profitable treatment of the ore in this province at present. The Kootenay Central railway, now being built, will eventually give transportation to silver and lead mines in parts of the district now without it.

Ainsworth.—This and the following named divisions in West Kootenay appear to have a brighter immediate future. Spokane men have secured and are opening several Ainsworth properties, and the Consolidated M. & S. Co. has bonded others. Arrangements are being made to resume work and ore production at the Bluebell, which is a big lead mine situated across the Kootenay lake from Ainsworth. The Utica, 12 miles west of Kaslo, is shipping ore, and The Deep Mine, Ltd., is extensively developing the deep of the Whitewater group properties, with the object of making tonnage available when concentrating and trans-

portation facilities, destroyed by forest fires in 1910, shall have been replaced.

Slocan.—The mine not having a railway connection, production of zinc ore from the Lucky Jim was not practicable, so development only was undertaken. No. 6 level, 400 ft. below No. 5, was driven 1134 ft., entering the 'lime dike', in which search for zinc is in progress. Rambler-Cariboo opened three shoots of silver-lead ore on each level at 900, 1000, and 1200 ft., respectively, and is extending the 1400-ft. level to find the same shoots. The concentrating plant is being removed down to a new millsite near the railway being constructed to provide transportation for this mine and the Lucky Jim. The development of much ore of good grade in lower levels of the Rambler-Cariboo is considered to have a most important bearing on the future of the Slocan district, this having proved that ore continues to depth. The Washington was further developed; it has much lead-zinc ore in its workings. The Payne is having a cross-cut driven 3300 ft. to cut the vein at 675 ft. below the lowest old level. Cody camp was active. Shoots of silver-lead and zinc ore were found in the Noble Five. The Reco opened a new shoot of ore in virgin ground on No. 11 level. The Twilight also found ore in its No. 2 adit. The Sunset continued driving No. 8 level 1600 ft. to reach a long shoot of ore worked for 300 ft. in length on higher levels. The Surprise passed through good ore when raising from adit at 1100-ft. depth to connect with the bottom of the old shaft 830 ft. above. About Sandon, at the Ruth-Hope the upper levels have been extended, and a lower adit driven 800 ft., while more than 500 tons of silver-lead ore has been shipped. The Richmond-Eureka has continued development and shipped about 2300 tons. A new company has been organized to work the Slocan Star, on which the old workings have been reopened, and a deep-level adit is being driven to cut the vein in 2300 ft. at 630 ft. below No. 5 level. Four-Mile creek mines are flourishing. The Standard has cut good ore in No. 6, which is 190 ft. vertically below the big galena showing on No. 5; has constructed an aerial tramway 8000 ft. from mine to millsite near Slocan lake, equipped a 100-ton concentrating mill, put in a water-line and an air-compressor, and has commenced production on a larger scale. The Silverton Mines, Ltd., has opened much ore on four levels down to No. 7, connected by raises up to No. 4, found rich ruby silver occurring freely in the ore, renovated the Wakefield concentrating mill, and been making experimental runs with one unit of the Elmore vacuum process plant on zinc middling from jigs. The Van Roi, which commenced concentrating at its new mill in March, put about 30,000 tons of ore through the mill and made two marketable products, namely, silver-lead and silver-zinc concentrates. The British Columbia Copper Co. bonded a gold property situated above Slocan lake and commenced developing it. Many other mines in Slocan and Slocan City divisions were worked, as well as those above mentioned.

Nelson.—In this division, further development of the Molly Gibson has been favorable, and the outlook for the mine much improved; it is owned by the Consolidated company, which has put its mill in running order and increased the power available for mining purposes. No information has been received from the Granite-Poorman gold mine, in connection with which some sensations were sprung on the public in 1911 by a local newspaper. The Wilcox, Yankee Girl, and Dundee, all in Ymir camp of this division, were worked. The Yankee Girl sent 1350 tons of ore to the smelter before it passed into the hands of a receiver; it has since been acquired by Spokane men. The Emerald, near Salmo, shipped nearly 2000 tons of lead ore. The Consolidated company bonded some claims in this district on which there is a big surface showing of lead carbonate ore. The Queen opened its gold-bearing vein down to greater depth; the Nugget milled between 3000 and 4000 tons of gold ore having a gross value of \$20 per ton; the Mother Lode proved its veins down to 500-ft. depth and put in a modern 10-stamp gold mill; and the Kootenay Belle and others were further developed.

The Arlington and Second Relief, at Erie, were also producers of gold ore.

Rossland.—The chief developments here were in the Centre Star group, owned by the Consolidated company, and the mines of Le Roi No. 2, Ltd. The former found the high-grade ore opened in the bottom of the War Eagle develop into quite a large body, and the average grade to keep up beyond expectations. Smaller orebodies were opened in other parts of the Centre Star group. The Le Roi No. 2 discovered and developed the Holywell vein on the 300 and 500-ft. levels, and opened much ore in the Rodney vein on the 1200-ft. level. The 1300-ft. level was extended, and preparations were made for going deeper. Le Roi No. 2 shipped 27,000 tons of crude ore to the smelter and concentrated 18,000 tons, producing 1600 tons of gold-copper concentrate. The Le Roi was sold to the Consolidated company; lately it has been shipping 100 tons of ore per day, and an early increase in tonnage is expected. The Bluebird and other small properties were also worked. At the Trail smelter and lead refinery the Consolidated M. & S. Co. of Canada put in two Dwight-Lloyd sintering units, rearranged the Huntington-Heberlein plant, and made numerous changes to facilitate handling and sampling ore.

Other West-Kootenay Divisions.—In Revelstoke division, mining is largely restricted to development of mica deposits and hydraulic mining for placer gold, both in Big Bend district. In the Lardeau, the Beatrice shipped 310 tons of ore, and in Trout Lake division the Silver Cup made an output of about 500 tons, also of silver-lead ore. Development was carried on at the Winslow, a gold claim, but there was little else worthy of note.

Boundary.—Tonnage of ore mined and smelted was the smallest for this district since 1907, due chiefly to the Crow's Nest miners' strike. The total was about 1,200,000 tons, as compared with 1,600,000 tons in 1910. The Granby company's production was 583,000 tons, as against 1,075,000 tons in 1910; the Snowshoe also produced less—31,000 tons, as compared with 147,000 tons in 1910. On the other hand, the British Columbia Copper Co. increased its output 95,000 tons, making it 533,000, as compared with 438,000. Little development was done in the Granby mines during the calendar year, for they were closed for several months, but in the fiscal year, ended June 30 last, the estimated additional tonnage of ore blocked out was 1,248,000 tons, while only 957,000 tons was shipped, consequently, ore in sight was increased 291,000 tons, making total ore "estimated in sight" 6,720,000 tons. Notwithstanding the reduced tonnage treated, smelting costs were three cents per ton lower. A new method for the disposition of slag, previously dumped molten, was arranged for while the furnaces were out of blast. This consists principally of granulating the slag by water, sluicing it to central storage bins where it will be dewatered, and conveying it on belts up to 100 ft. above the old dump. Dump room for six to ten million tons is thus provided. Most of the B. C. Copper Co.'s ore treated came from its Mother Lode mine, in which a different method of mining was adopted. The orebody was divided into a series of transverse slopes of a maximum width of 25 ft., thus making available a greater percentage of the ore and reducing costs of extracting it. Under this system more than 100,000 tons of ore was broken down at one time last autumn. In this connection, 2433 holes were drilled, these averaging approximately 14 ft. each in depth. These were charged with 425 boxes of 40% dynamite, a total of 103½ tons; 2525 low-tension No. 7 electric detonators were used connected in series of 25; connection was finally made to 550-volt current, and the whole exploded. The year's tonnage from the Mother Lode was about 315,000 tons; while from the New Dominion Copper Co.'s Rawhide mine, 172,000 tons was obtained, and 46,000 tons from three other Boundary mines owned by the company. In addition, 15,000 tons from two mines in Washington, also owned by this company, was smelted. Three furnaces were kept in blast nearly all the year, using Pennsylvania coke until November, when one was blown out to economize in coke consumption until a

supply should be obtainable from Alberta. Work was resumed in the Emma mine after a long shut-down, and about 2500 tons of ore shipped to smelter monthly. During the year several properties were bonded and exploration carried on; among these was the Voigt group of 63 claims in Similkameen district, which, it is hoped, will develop into a big copper mine. The Greenwood-Phoenix Tramway Co. extended its adit to 3000 ft. from the portal, and the Argo company also drove a long tunnel, but there was little else noteworthy.

Similkameen.—In metal mining, the Hedley Gold Mining Co. was the only one that produced ore. Tonnage from its Nickel Plate group of mines was approximately 57,000 tons, milled at its 40-stamp mill at Hedley, as compared with 46,800 tons in 1910. Average value per ton was \$12.10 and percentage of extraction 92. This shows a recovered value four cents per ton higher than in 1910. No gold is saved on amalgamation plates, but about 75% recovered is by concentration, and 25% by cyanidation. The treatment process includes crushing by stamps, tube-milling, cyaniding, and saving of gold in Merrill standard 36-in. filter-presses with Oliver filters for the slime. The production of concentrate is about 300 tons per month. The product, which runs high in gold, is reduced at Tacoma. Development during the year added largely to known reserves. The lower levels of the mine look well, and pros-

NICKEL PLATE MINE, HEDLEY, BRITISH COLUMBIA.

pects for 1912 are bright. Coal was shipped from a small colliery at Princeton, and a promising new coal mine was opened above Granite creek, Tulameen.

Coast.—Quite a transformation has been effected in the Britannia mine, Howe sound. Two years ago the outlook for this property was discouraging; now there is in sight a large tonnage of ore running 4 to 5% copper, and it is believed the development in the early future will greatly increase known good ore. More than 100,000 tons of ore was extracted; most of this was passed through the graded crushing and concentrating mill. Extraction was good, for chalcopryite ore, about 80%. A full-sized working unit of the Elmore vacuum process plant gave excellent recoveries, indicating that treatment of fine material and slime, following hand-sorting and jigging, will bring the total extraction of value up to a high percentage.

Another important advance was that of the Granby Con. M. S. & P. Co., at its Hidden Creek copper mine, Observatory inlet. Reports of six engineers show an estimated reserve with a minimum of 6,000,000 and a maximum of 12,000,000 tons, averaging 2% copper for the smaller and 1.65% for the larger tonnage. Since their examinations of the mine, further development has given additional reserves estimated to include at least 200,000 tons of 5% copper ore besides that of lower grade. The company has had up to 270 men preparing the mine for stoping and production, and carrying out surface improvements. Establishment at Goose bay, near the mine, of a copper smelter, with blast-furnace capacity of 2000 tons per day is planned. The year's results in Portland Canal district have been disappointing. The only mine that made production on a commercial basis was that of the Portland Canal Mining Co., from which ore was extracted that, when concentrated in the company's mill, gave rather more than 2000 tons of concentrate, the bulk of which was a product

running 12 to 15 oz. silver per ton and 7 to 11% lead. The year's results demonstrated that to be profitable, milling operations must be on a much larger scale. The Red Cliff was reported to have developed much copper ore of good grade, but bulk shipments to the smelter, frequently talked of, were not made. Other properties were stated to be looking well, but they are without transportation facilities. In Skeena River district, numerous silver-lead claims were more or less prospected; in some cases development into shipping mines is confidently expected. Most of these are within a radius of twenty miles of Hazelton. Railway transportation will likely be available for some of them in 1912.

The Tyee Copper Co.'s smelter, which is situated at Ladysmith, Vancouver Island, was operated intermittently throughout the year, but the available supply of ore was insufficient to keep the furnaces in blast continuously. The ore smelted came chiefly from British Columbia coast mines, and others in southern Alaska.

Prospects for Future.—For metal mining, the outlook is fairly encouraging. More gold and silver should be produced from Nelson, Rossland, Boundary, Similkameen, and the Coast mines; silver and lead in larger quantity should be mined in the Sloean district especially, and to a smaller degree in East Kootenay and Skeena district; the Coast mines promise a greater output of copper, but known inland mines will hardly make any increase; zinc production was so small in 1911 that it will not be difficult to make a considerable advance.

Gold-Dredging in the Philippines

By CHARLES JANIN

The Paracale district was the only field in the Philippine Islands up to a short time ago in which dredges had been even partly successful, for none of the present boats can be properly classed as entirely successful. As to the present time, according to R. Y. Hanlon, in the *Mining and Scientific Press* of August 26, there is only one dredge working in the district and another dredge idle on account of litigation. Both of these dredges are of New Zealand design and manufacture. They are equipped with 5-en. ft. open-connected buckets, work on a headline, and are operated with steam-power, each using about 3 cords of wood per day. Their efficiency is low, less than 1000 cu. yd. per day. The dredge of the Paracale Gold Dredging Co. has worked about six acres of an average depth of 45 ft., making a total of about 450,000 cu. yd. The gold won from this acreage has been, according to Mr. Hanlon, \$20,000, showing a saving of about 45c. per yard. The extraction is estimated from 50 to 75%. The property of this company, including the Melville, Fingal, and Nueva California properties, was acquired late in the year by New Zealand capitalists, who have had the ground drilled and are preparing to build additional dredges. The Malaguit river in Ambos Camarines offers some opportunities as a dredging field. The depth of the ground where the Philippine Gold Dredging Co.'s dredge is working on the river, about four miles from the sea, is from 18 to 24 ft. The dredge is a Risdon boat with 3½-ft. buckets. The average amount handled per month is between 15,000 and 20,000 cu. yd., and the gold content of the ground is about 25c. per yard, of which approximately 75% is recovered. The working cost, exclusive of depreciation, office expenses, and interest, is about 10c. per cubic yard, but, owing to the fact that no record is kept of anything except the actual amount of gold won, an accurate estimate is impossible here as on the Paracale dredge where the same methods are employed. A new installation for the Islands, now under construction by the New York Engineering Co., is a 5½-ft. steam-driven dredge for the Gumans river in the Paracale district. This will be the first large modern dredge in the Islands, and its success will undoubtedly give an impetus to dredging in that country. According to the builders, the ground was prospected with Empire drills, and sufficient gold found to warrant the erection of this equipment.

The dredge will cost about \$150,000 complete, and will be fitted with a wooden hull, as the life of the property with the one dredge is estimated at five years. It is believed that with a company with sufficient capital to operate several modern dredges under efficient management, a large portion of the district could be profitably dredged, and, under these conditions the working cost should not exceed 7c. per cubic yard.

Coal Mining in British Columbia

By E. JACOBS

Substantial advance was made in coal mining during the year. The Western Fuel Co., at Nanaimo, made the largest output in the history of its mines—about 586,000 long tons, as compared with nearly 513,000 tons in 1910. This company is opening a new shaft mine about four miles south of Nanaimo. Main and air-shafts are being sunk to a depth of about 1000 ft., and it is expected that coal will be reached next autumn. Thereafter, the mine will be rapidly developed to a producing capacity of 1200 to 1500 tons per day. The company's mines are in excellent condition as regards equipment, development, and prospects, and it is expected that 1912 will prove a record year. Distribution of coal produced was approximately as follows: Sold in British Columbia, 59%; in California, 32%; elsewhere, 9%. The Canadian Collieries (Dunsmuir), Ltd., maintained production at about the same rate as in 1910, when the output was nearly 900,000 long tons, of which 122,000 tons was exported to the United States and 26,000 tons to other countries. The distribution of the 1911 production was somewhat similar. The company has let contracts for construction in connection with the development of a hydro-electric water-power, initial capacity to be 11,000 hp. Contracts let include that for a dam and a water-line about three miles long. Power will be used at the company's several Union Colliery mines in the vicinity of Cumberland, Comox district. A new shaft is to be opened, but as the shaft, sinking of which has been commenced, will have to be sunk about 1000 ft., no production from here will be made for about 12 to 18 months. Many changes and improvements have been authorized, and these are being carried out as rapidly as practicable. Production is to be materially increased and more of the company's large deposits of coal utilized. The Pacific Coast Coal Mines, Ltd., has increased production at its Fiddick colliery to about 20,000 tons per month, and has active demand for all the coal it mines. At its Suquash colliery, development is being continued to get the property in shape for shipping coal. The Vancouver-Nanaimo Coal Mining Co. is providing shipping facilities at tidewater for the coal it mines at its New East Wellington colliery.

The chief development in Nicola was in the coal mines. The Nicola Valley Coal & Coke Co. erected and equipped new tipple, increasing the coal-handling capacity to 1000 tons per day; put in new machinery and plant; extended railway trackage; much improved outlets from mines; and found, by means of diamond-drill, important extensions of coal deposits. The output tonnage was in excess of 200,000 tons, as compared with 141,000 tons in 1910. Development of several other properties was continued, but production was small.

In the East Kootenay production of coal was practically stopped during the eight months the coal-mine employees were on strike, but in that period coal deposits were developed at a level 500 ft. above the main entry to the Hosmer mine. Several new seams were opened at the Crow's Nest Pass Coal Co.'s Coal Creek colliery, and others at Carbonado. The Corbin company opened an enormous deposit of coal occurring 3000 to 4000 ft. along the surface and 300 to 400 ft. wide, which will be mined in open workings.

More work was done on coal properties in the Telkwa and Morrice River district, while in the northern part of Skeena district much anthracite coal was found and partly developed. Prospecting for coal and oil on Graham island of the Queen Charlotte group was done on various holdings.

Review of Mining in 1911 in the Various States and Districts

California's Mineral Industry

By WILLIAM H. STORMS

Although the statistics of the mineral production of California for 1911 are not, and will not be available for several months, there seems little doubt that the aggregate output for the past year will equal, if not exceed that for the year 1910. There was during 1911 a noticeable increase in activity in gold mine development and operation, the impetus being partly to the surprising developments in old mines on the Mother Lode, where new ore-shoots have been exploited at great depth in unexpected places. Another stimulus to gold-quartz mining has been the successful operation of several rich mines in the northern portion of the State, particularly in Shasta and Sierra counties, and at least one gold mine has been brought under successful operation in Modoc county near Fort Bidwell. To these may be added several new and successful drift-mines in various parts of the north end of the State, and the encouragement resulting from the promising development

done more than any other thing to instill confidence in the minds of investors. There are so many instances of success where the enterprise has been in competent hands, that deep mining for gold in California is now considered as not only legitimate, but as offering as safe an investment, in many cases, as can be found in any other kind of business. At the same time, viewed from the speculative standpoint, there is nothing else that offers anything like as great possibilities in the form of profits. Deep mining anywhere, whether for gold, copper, salt, coal, or any other mineral, requires large capital, experienced management, and a fair amount of good fortune. Those of limited means cannot hope to equip and develop mines where a quarter to half a million dollars, or perhaps twice the latter sum, will be required. There are, however, many opportunities for the smaller investor where a few thousand dollars will prove a property to be either valuable or worthless, and unusual activity in mines of this class is now noticeable. Generally speaking, therefore, gold mining throughout the State is in a decidedly healthy condition, and it is my belief that this branch of our mineral industry is going to

LILA C. BORAX MINE IN SOUTHERN CALIFORNIA.

of new prospects in numerous old districts. Ever since the early days of gold mining in California, prosperity in this industry has swept over the State in a series of waves. The successful outcome of many of the earliest ventures resulted in a general organization of mining companies and the equipment of a large number of prospects, good and bad. The natural result followed. Some were successful, many were not, and in a few years gold mining came into disrepute. After a lull in mining investment, much of which has been ill advised or not advised at all, new successes were achieved, and again gold mining became popular. This has been the history of gold mining in California throughout the past six decades. In recent years a wave of this character was distinctly observable. In 1890-91, gold mining in the State was at a very low ebb. Then came the fortunate development of the Kennedy mine at Jackson, and the phenomenal discoveries in the Rawhide mine near Jamestown, in Tuolumne county, followed by rich developments in the mines at Angels, particularly in the Utica group. These, and several other notable successes, together with the stimulus given gold mining throughout the world by the important operations at Cripple Creek, Colorado, and the wonderful developments on the Rand in South Africa, gave the gold-mining industry of California a decided impetus, and a campaign of development, particularly on the Mother Lode, was inaugurated which was without precedent, since the days between 1850 and 1865. As a result of this unusual activity numerous valuable properties were developed, and as usual a far greater number proved unsatisfactory. An analysis of the numerous misadventures will show, in most cases, good and sufficient reasons for the lack of success; nevertheless, some of the failures of those years have since developed into the bonanza mines of today, and it is these latter that have

forge ahead, with the result of a largely increased output within the next few years.

For several years past the oil industry has steadily increased in importance, until it has become the most important of the several branches of the local mineral industry. Just at present there is a noticeable retardation in development as compared with two or three years ago. This is due to various causes, partly to the attitude of the Government in the matter of locating oil lands, and partly to the tremendous and unexpected production of several spouting wells, among these latter the famous Lake View gusher. A few more wells of this description would put small producers out of business. Fortunately, for the industry, perhaps, these abnormal wells are generally short lived. That all of the oil-bearing territory in California has been discovered, I do not believe, and such belief is strengthened by recent developments in several fields. As long as eighteen years ago, I asked a prominent oil operator if he did not think there were still splendid chances for oil in certain undeveloped districts. His reply was to the effect that if the untried territory was worth anything, he and his company would know of it. Since that time, in the territory referred to has been developed some of the most productive fields in California.

The copper industry of the State is among the most important, the output for 1910 having been 53,600,000 pounds. The closing of certain smelters by the courts because of damage by smelter fumes has reduced the output of copper somewhat, but the problems involved are, apparently, in a fair way to be solved. Several experienced engineers are working industriously in an endeavor to abate the nuisance, and if these efforts are successful, it will undoubtedly result in increased activity in the copper mining industry in California.

The structural materials of the State, of which there is a large variety, and of which the quality is excellent, are constantly coming into more extended use as their merits become better known to those contemplating building. Undoubtedly the Panama-Pacific Exposition will do much to call world-wide attention to the advantages of employing California building stones, ornamental marbles, porphyries, and other varieties for interior decoration; also cement, magnesite, and the several varieties of terra-cotta and bricks. At the present time there is being erected in the State Mining Bureau in the Ferry building at San Francisco, a most interesting exhibit of structural materials. The collection includes several varieties of granite, sandstone, marble, terra-cotta, cement, magnesite flooring, and a beautiful fountain constructed of California cement. These materials have been cut and dressed or otherwise prepared to form parts of several independent structures. All who contemplate the erection of a building of any sort, are invited to visit the Mining Bureau and inspect this exhibit, and they will gain thereby valuable knowledge concerning the possibilities of structural materials of California. The several portions of the exhibit have been donated by the various concerns actually engaged in producing or manufacturing them from crude materials, all of which are obtained in California. On the whole, the outlook for the mineral industry of the State is most encouraging, and a noticeable expansion may confidently be expected along many lines.

Gold-Dredging in California

By CHARLES JANIN

The total amount handled by the California dredges during 1911 will closely approximate 65,000,000 cu. yd. This will be the more appreciated when it is stated that it is equal to, and perhaps in excess of, the total combined yardage handled by all the dredges in the world, outside of California. In this connection the following table of approximations for 1911 for gold dredges in different countries may be of interest:

Country or State.	Dredges working.	Approx. yardage.	Approx. value.
California	61	65,000,000	\$7,850,000
Victoria	57	14,000,000	1,500,000
New Zealand	100	14,000,000	1,500,000
Alaska and Yukon..	40	8,000,000	3,200,000
Russia	60	11,000,000	2,000,000
Montana	7	6,000,000	700,000
Colorado	3	3,000,000	350,000
Idaho	7	2,000,000	200,000
Other fields	6,000,000	1,000,000

During 1910, the production of gold won from dredging operations in California was \$7,550,254, being an increase of \$173,304 over the output of 1909. There were 61 dredges in operation during the year, and the combined yardage handled approximated a total of 60,000,000 cu. yd., which would indicate an average recovery of 12½% per cubic yard. The production of Butte county, as prophesied in the review of last year, fell behind that for 1909, and the first place was taken by Yuba county. Butte will probably show a still further decrease for 1911, as much of the best ground has been worked over, and several of the dredging companies are fast approaching their end. The new 15-ft. boat of the Feather river division of Natomas Consolidated will add materially to the yardage handled for that company, but for the reasons above stated it is not expected that the total gold production of the county will be increased. The highest production for Butte county was reached in 1908, and since then there has been a considerable decrease.

Yuba county showed an increase of \$730,557 over that of 1909. The Yuba Consolidated Gold Fields had a most successful year, their 12 dredges handling for the 12 months ended February 28, 1911, 13,970,728 yd., which yielded \$2,927,246. Yuba No. 13 dredge was put in commission August 10. This dredge is equipped with 15-cu.

ft. buckets and is the largest dredge in the world, digging to a depth of 65 ft. below water-level. The dredge was built by the Yuba Construction Co., the Bucyrus company furnishing much of the machinery. The actual capacity of the dredge has exceeded at times 65,000 cu. yd. per week. Yuba No. 10, a 7½-ft. dredge, was destroyed by fire November 10. The details have not been made public, but it is thought that the fire occurred at the transformers. Electric current was taken on the boat at 4000 volts and stepped down to 440 volts at the transformers for use on all motors. The Marysville Gold Dredging Co. dismantled Marigold No. 2 during 1911, which was said to be too light for the deep ground, and put in commission in April, No. 4, an 8½-ft. boat built by the Union Iron Works. This dredge has been fully described in the *Mining and Scientific Press*, December 9, by R. E. Cranston.

In Sacramento county the Natomas Consolidated put two 15-ft. dredges in commission, Natoma No. 8 in January, and No. 9 in August, and is constructing Natoma No. 10. No. 8, after operating successfully on Rebel hill, in ground which, on account of partly cemented gravel, and the presence of considerable clay, was formerly considered too difficult to be economically dredged, was destroyed by fire October 23. This dredge, differing from Yuba No. 10, also destroyed by fire, took electric current on board at 2200 volts for all motors. The fire was, as near as could be ascertained, caused by an explosion at the oil-switch. The sea-valves were opened when it was found impossible to extinguish the fire, and the hull sank. The digging ladder dropping down prevented the front end, and the sand tailing the rear end, of the dredge, from a total submersion, so that much of the machinery was destroyed. It is now being wrecked by the Yuba Construction Company.

The loss of dredges by fire in California has not been great. These two dredges are the first lost from this cause for several years. Viloro No. 1 was destroyed in September 1909, and the Shasta Dredging Co. lost a dredge in June 1908, both being from fire caused from some derangement of the electric current. In connection with the fire on Natoma No. 8 and Yuba No. 10, it is interesting to note the different manner in which electricity was taken on the dredge. On Natoma No. 8, current was supplied direct to the motors at 2200 volts, while on Yuba No. 10, it was stepped down on the dredge from 4000 volts to 440 for use at all motors. There was pointed out in Bulletin 57 of the State Mining Bureau on 'Gold Dredging in California,' written by William Winston and myself, the advisability of keeping sand within easy reach for use in case of electric disturbance at transformers, and a suggestion was also made that an automatic sand-box arrangement for extinguishing any fire at the transformers be provided. It would certainly be advisable to use one of the varieties of asbestos board in building a fireproof shelter around the transformers, or oil switch. This practice is being followed on some dredges since the fire. In addition to this, I believe that liquid stone paint can be advantageously applied to exposed woodwork in the vicinity of the oil-switch, etc. The best safeguard would be to have the dredge hull and housing made of steel, and this practice will probably be adopted on future large boats. On the old dredges, I believe, in addition to the precautions suggested, that an auxiliary fire apparatus consisting of a gasoline engine with fire pump and hose which could be started at a moment's notice, would be advisable. At the present time, if a fire occurs from the electric current, the motors are of course out of commission and the pumps are of no use.

Besides the dredges of the Natomas company, the Ashburton company is operating a 7-ft. dredge in Sacramento county; details of operations are not made public. The boat is reported as digging approximately 800,000 cu. yd. per year. The Union Dredging Co. is constructing a 9-ft. boat for its property. This will be in operation in 1912. Reports of dredging from other counties have indicated a prosperous season. Of the outside counties, Trinity is perhaps attracting most attention. The Alta Bert company has started its dredge, and two other dredges are in course of construction; besides this, several areas are being

prospected in the county with a view to installing dredges if results are satisfactory. The record of dredges in California for 1911 is as follows. 8 put in operation, including 2 that were moved; 2 dredges destroyed by fire; 3 sunk or put out of commission by accident; 3 shut down; and 6 under construction at the end of the year. Following is a table showing the distribution of dredges in California at the close of 1911, also those constructing, and those that were dismantled or destroyed during the year:

County.	Dredges operating.	Destroyed or shut down.	Under construction.
Butte	26	3	1
Yuba	13	3	..
Saeramento	9	1	2
Calaveras	2	1	1
Siskiyou	1
Shasta	1
Merced	1
Stanislaus	1
Placer	1
El Dorado	1
Trinity	1	..	2
Total	57	8	6

Hulls.—One interesting feature of dredge construction during the year is the fact that Natoma No. 10 is being

YUBA NO. 13, ONE OF THE NEWER BOATS BUILT BY THE YUBA CONSTRUCTION COMPANY.

built on a steel hull. Until recently there has been little incentive to resort to steel hulls in California, but with the growing scarcity of timber and the demonstration that the wooden hull has a shorter life than was anticipated, more attention is being paid to steel construction. In a number of cases where timber is readily available the wooden hull will still be found preferable, and the selection of the hull will be a matter of judgment after studying the conditions and the advantages possessed by each material. While the steel hull has been used for years on foreign dredges, and has been supplied by the Bucyrus Co., the Yuba Construction Co., and the New York Engineering Co. on dredges for foreign service, Natoma No. 10 is the first dredge with a steel hull built for the California field, and it is expected that any future large dredges will be built with steel hulls. Aside from the danger from fire, which has been particularly emphasized this year, the difficulty of getting suitable timbers for a hull of the larger size is becoming greater every year. While the first cost of a steel hull for the small and medium-size boats will be greater than for a wooden hull, steel hulls for the large dredges will probably cost no more than the wooden hulls in the first instance, and no doubt less in some cases. A few years ago it was customary to estimate the life of the wooden hull at ten years, but time has proved this a fallacy in many cases. The old Continental had a life of 10 years and 4 months, after having been refitted and overhauled several times, but wooden hulls in general require considerable attention after a few years of service. The ventilation of hulls has been greatly improved of recent years, and the life greatly in-

creased thereby. Ventilating fans at the stern force air-currents through either side of the hull, the air passing out through stand-pipes on the front of the dredge. On Yuba No. 13, an experiment has been made of placing salt in the hull, to take up excess moisture, etc., six tons of salt being used for this purpose. Three accidents in California and one in Oregon, due, or partly due, to defective hulls, are reported for this year. Lava Bed No. 3, which had been operating nearly seven years, was put out of commission August 8 by the tailing pile sliding down on the dredge. The old hull could not stand the strain and the dredge sank. The hull of Pacific No. 1, in Oroville, after a life of 5½ years, sank December 3; and Calaveras No. 1, near Jenny Lind, after a life of 8 years, sank December 11. The Champlin dredge on Foote creek, Jackson county, Oregon, sank in November, also from a defective hull.

Another interesting change in construction is shown in the spud arrangement on Natoma No. 10. The steel spud will be placed directly in the centre of the stern end of the boat. The strain will thus be more evenly distributed. A second spud of wood placed on one side will be used for stepping ahead, as on the other dredges. Dredge construction of recent years has not, with the exception of increasing the size of the buckets, which was discussed in my paper of October 14, been so much a matter of radical change in design as it has been an endeavor to use better material and to strengthen all wearing parts of the dredge, thus increasing the working time, and lowering the operating cost. To this end operators and builders have worked in coöperation and have succeeded in building, if not a perfect dredge, at least in establishing a type that is recognized as the standard dredge the world over. It is interesting in this connection to note the total number of dredges built by the different American companies. According to what information I have, the Bucyrus company has built or furnished machinery for 80 dredges, the Risdon Iron Works built 70 and reconstructed 2, the Union Iron Works 7, the Marion Steam Shovel Co. about 30, the Yuba Construction Co. 28, the New York Engineering Co. has built a number, and several have been built by smaller construction companies whose output is not known at the present writing.

All dredges now built in California are equipped with close-connected buckets, revolving screens, and belt-conveyor tailing stacker. While a dredge of the same general design as that followed in the California fields can be built of

FOREST HILL DREDGE, A 31½-FT. BOAT BUILT BY THE RISDON IRON WORKS AND OPERATING ON AMERICAN RIVER.

lighter material, it is obvious that the life of those parts subjected to great wear, as proved by California experience, will be shortened. Perhaps in some districts a light well constructed dredge might be the most suitable, but experience in general has demonstrated that strengthening the wearing parts in the first instance is better policy than frequent renewals. The first cost of a dredge should not be considered a matter of such vital importance by the intending purchaser as is often the case. If by strengthen-

ing and increasing the weight of certain parts that are subjected to great strain or wear, the first cost of a dredge is increased \$15,000, or \$20,000, or even more, it is obvious that a saving of even $\frac{1}{2}$ c. per cu. yd. in working cost, by reason of greater capacity, made possible by less loss of time for repairs, etc., to say nothing of the greater cost of repairs for the light boat operating under the same conditions, would soon compensate for the increased initial outlay.

Dredges Being Constructed.—The Gardella dredge being built by the Union Iron Works for Lawrence Gardella on the Downing tract at Oroville, will not be quite finished in 1911, but will probably commence operations early in January 1912. This is a 5-ft. boat, designed to dig 35 ft. below water-level. The construction of the 9-ft. dredge of the Mokelumne Mining Co. was delayed on account of financial difficulties, and the property has recently been taken over by J. W. Goodwin, who has had considerable prospecting done during the year on the Mokelumne and nearby properties. It is expected that the dredge will be operating early in 1912. The construction of the E. L. Smith dredge at Weaverville, Trinity county, has also been delayed, and this dredge will not be operated until 1912. The dipper dredge on the Poker property, in Trinity county, will also be in operation in 1912. The Bucyrus Co. is building a 9-ft. dredge for the Union Dredging Co. on the Fassler ranch near Folsom, adjoining properties of the Natomas Consolidated. This dredging company has invited some criticism by the methods employed in promoting its property, but it is said that the management has been taken out of the hands of the original promoters, and it is proposed to have the operations under competent technical direction. Natoma No. 10, which will be put in commission in April or May 1912, is the first dredge to have a steel hull in California fields. This dredge will be equipped with 15-cu. ft. buckets. The steel hull will be 150 by 56 by $10\frac{1}{2}$ ft., and will have a total weight of 920,000 lb. This is about one-half of the weight of a wooden hull to carry the same machinery. The Scott River dredge, which was moved by the Union Construction Co. from Siskiyou to Trinity county, commenced work in December. This is a $7\frac{1}{2}$ -ft. boat, and its previous operations proving unsuccessful, the dredge was shut down. It was afterward bought by the Alta Bert Dredging Co. for ground near Trinity county. The Butte Dredging Co., having worked out its ground near Oroville, moved the dredge to Jenny Lind, Calaveras county. The dredge has been equipped with a new bucket-line of 4-ft. buckets, and commenced operations on the new ground in December. The Poker Bar Dredging Co. moved a Marion dipper dredge, which had formerly operated at Oroville, to Poker Bar, Trinity county, but has not yet completed the new boat.

Dredges Dismantled.—The Marysville Gold Dredging Co. shut down Marigold No. 2. It is said that this boat proved too light for the ground being dug. The Yuba Consolidated Gold Fields shut down Yuba No. 2, using some of the machinery in repairing No. 1, which is of similar design, and will probably also be dismantled in the near future. L. & J. Gardella dredge was dismantled, part of the machinery being used on Gardella No. 4. Lava Bed No. 3, Pacific No. 1, and Calaveras No. 1, were sunk or put out of commission by reason of accidents to defective hulls. Natoma No. 8 and Yuba No. 10 were destroyed by fire. Machinery from the dismantled Bear River dredge has been moved to Oroville, where it is expected it will be utilized later in the construction of a new boat. The Bear River property has been a great disappointment to the English stockholders of Oroville Dredging, Ltd. Originally expected to yield 12c. per cu. yd., three dredges have been tried on this ground without success. The last dredge, a 7-ft. boat, handled, for the year ended July 31, 1910, 994,876 cu. yd. at a stated cost of 6.26c. The ground worked gave an average recovery of 4.71c. per cu. yd., so the operating loss was 1.53c. per cu. yd., or about \$1200 per acre.

Working Costs.—Mere figures of operating costs may be of some interest, but are really of little value unless accompanied by detailed statements, and such are not always

made public. The working cost of a dredge might show considerable variation for different years, and the cause not be apparent unless such information was furnished. In this regard the following example is pertinent: In the report of Oroville Dredging, Ltd., for 1910, mention is made of Exploration No. 3, a 7-ft. dredge which handled 1,228,110 cu. yd. during the year, working to an average depth of 34.5 ft. The average working time was 19 hours and 56 minutes per day, and the operating cost 4.16c. per cu. yd. "The cost of operation was reduced 1.54c. per cu. yd. (over that of the previous year), practically all of which reduction was due to the fact that the bucket-line had been overhauled and charged against the previous year's work." The average cost of the dredging operations of Oroville Dredging, Ltd., in handling 5,661,612 cu. yd. for the year ended July 31, 1910, was 5.05c. per cu. yd. The Yuba Consolidated Gold Fields handled for the year ended February 28, 1911, 13,970,728 cu. yd. at a total cost of 5.67c. per yd. The Natomas Consolidated Co. has dredged, from January 1, 1909, to June 30, 1911, a total of 44,542,141 cu. yd., with an average recovery of 9.82c., and an operating cost of 4.13c. per cu. yd. Of this, 15,989,525 cu. yd. was dug during 1910, at a cost of 4.52c. per cu. yd., and 10,793,891 cu. yd. during the six months ended June 30, 1911, at a cost of 3.77c. per cu. yd. The lowest operating costs of record are those of a $13\frac{1}{2}$ -ft. dredge operating in the Sacramento valley under extremely favorable conditions. This boat handled, from May to December, 1908, 1,830,201 cu. yd. at a cost of 2.3c. per cu. yd., and from January 1, 1909, to November 1, 1910, a period of 18 months, 5,814,975 cu. yd. at a cost of 2.74c. per cu. yd. None of the 15-ft. boats have as yet been operating long enough to make the figures of operating cost of permanent value.

While most of the gravel areas suitable for dredging in California have been examined in the interest of dredging companies, there are areas which a few years ago were considered too low-grade for economic dredging, that will, on account of the great advance made in dredge construction, and the consequent reduction of working costs, be again considered. In this connection it is interesting to note that a number of examinations were made during 1911. The success attending the moving of the Scott River, the Butte, and the Poker Bar dredges, will no doubt encourage some of these dredging companies, whose property is fast approaching an end, to look for other areas. On some properties coming under my own observation, there have been certain parts which, if segregated from the balance and offered at a reasonable price, would be worthy of serious consideration by a dredging company, which having exhausted its own holdings, was in the possession of a good dredge, valuable experience in dredging matters, and what, perhaps, is the most important, money in the treasury. The machinery of a dredge, if in good condition, can be moved and refitted on a new hull in some cases at less than one-half of the cost of a new boat, and the resultant dredge be well suited for the conditions under which it is to operate. Altogether, with the advance made in dredge construction, the reduction of working costs and the probable increase in size of the dredge buckets to one cubic yard, enabling the working under favorable conditions of areas that could not have possibly been previously considered as dredging ground, and the possibility of working over some of the ground that was first dredged, the outlook for dredging in California is decidedly good.

Onyx deposits have been known to exist in east Tennessee for a long time, and attempts have been made at recurrent intervals to utilize the material. Thus far no success has attended these efforts, but with persistent frequency hopes are aroused over some new find and glowing announcements are made of the possibilities of this industry. The onyx found is of cave formation and for the most part represents the remnants of vanished caves. The character and extent of the deposits and the possibilities of their commercial development were discussed at the recent meeting of the Geological Society of America by C. H. Gordon.

The Year Among Nevada Mines and Mills

By L. F. ADAMSON

While the statement that Nevada owes her prominence today to her mining industries is trite, it cannot be truthfully gainsaid. In the past Nevada has suffered greatly from the 'wild-catter' and stock manipulator. They have probably done more to discredit the State and her paramount industry than all other opposing influences combined. But now, by legislative act, they have become possible to control, and may only apply their nefarious methods at such great personal risk that it has ceased to be attractive or profitable. The mining industry is therefore on a sound and attractive basis.

Complete official data of the mineral output of the State is not yet obtainable for the third and fourth quarters of 1911. The statistics here given are compiled from the sworn quarterly statements of the various operators, for bullion-tax purposes, and may be considered as very conservative.

The State's tonnage produced during the first six months of 1909 was 1,371,027, and during the same period for 1910, 1,930,977, an increase for 1910 over 1909 of 559,950 tons, or 41%. During the first six months of 1911 the tonnage production was 2,148,901, an increase for 1911 over 1910 of 217,924 tons, or 11 1/3%, and for 1911 over 1909 of 777,874 tons, or 57%. Tonnage produced during the second six months of 1909 was 1,535,796, and during the same period for 1910, 1,824,051, an increase for 1910 over 1909 of 288,255 tons, or 18 3/4%. The gross value of the ore production for the first six months of 1909 was \$13,234,692.77, and for the same period of 1910, \$15,026,432.35, an increase for 1910 over 1909 of \$1,791,739.58, or 13 1/2%. For the first six months of 1911 the gross value of production shows \$16,372,746.63, an increase for 1911 over 1910 of \$1,346,314.28, or 9%, and for 1911 over 1909 of \$3,138,053.86, or 24%. The gross value of ore production for the second six months of 1909 was \$11,734,838.40, and for the same period of 1910, \$16,576,750.19, an increase for 1910 over 1909 of \$4,841,911.79, or 41%. Statistics of tonnage and value by quarters from January 1, 1909, to June 30, 1911, are as follows:

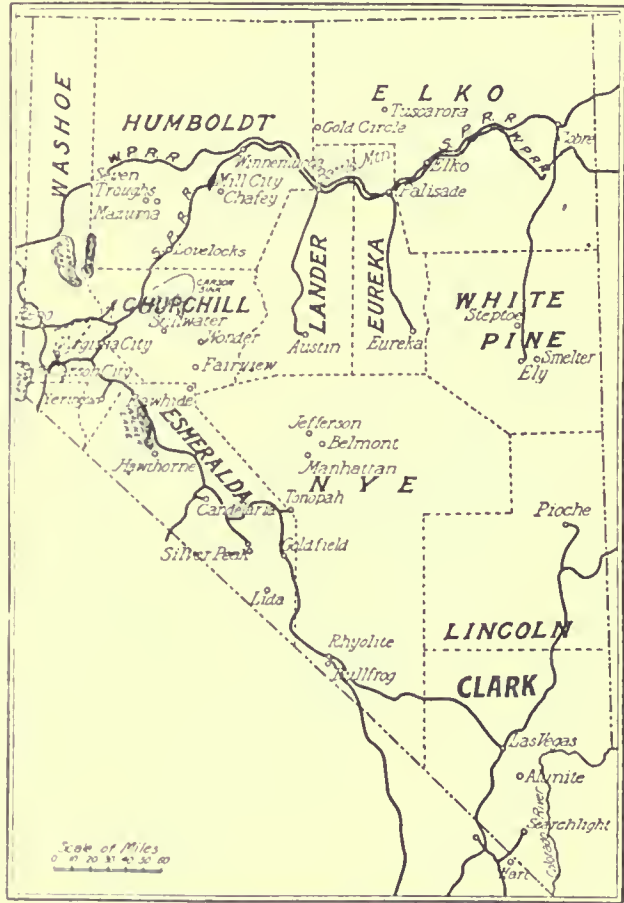

1909.	Tons.	Value.
First quarter	649,222	\$ 6,343,635.19
Second quarter	721,805	6,891,057.58
Third quarter	786,888	4,920,837.03
Fourth quarter	748,908	6,814,001.37
Totals	2,906,823	\$24,969,531.17
1910.	Tons.	Value.
First quarter	930,282	\$ 6,953,851.14
Second quarter	1,000,695	8,072,581.21
Third quarter	912,802	8,131,375.47
Fourth quarter	911,249	8,445,374.72
Totals	3,755,028	\$31,603,182.54
1911.	Tons.	Value.
First quarter	1,075,139	\$ 8,455,543.30
Second quarter	1,073,762	7,917,203.33
Totals	2,148,901	\$16,372,746.63

Clark County.—During the year ended December 31, 1909, Clark county produced a tonnage of 11,317, of a gross value of \$66,723.44; during the same period for 1910 the production was 36,894 tons, of a value of \$190,791.43; for the first six months of 1911 showed a tonnage of 2345, valued at \$36,447.23. The falling off evidenced at this time is largely due to the temporary suspension of the Quartette mine and mill of Searchlight. This is operated by a close corporation, and facts for public information are difficult to obtain. The property is a gold and silver producer and has thus far yielded over \$150,000, and, it is contended, still has large ore reserves in sight.

Besides numerous attractive gold prospects, this county, in the Searchlight, Eldorado, Yellow Pine, and Sunset mining districts, is liberally sprinkled with large deposits of silver-lead and zinc ores that will eventually bring it into great prominence.

Churchill County.—During 1909 the Churchill county product totaled 715 tons, of an aggregate value of \$54,228.03; during 1910, 54 tons, \$8209.30; and for the first six months of 1911, 12 tons, \$823.94. During the past two years, production in this county has scarcely been attempted, but extensive preparations have been made, particularly in the Fairview and Wonder districts, for future operations.

Esmeralda County.—Esmeralda county produced, in 1909, 627,870 tons of ore, of a value of \$11,466,677.85; in 1910, 459,801 tons, \$9,587,833.59; and during the first six months of 1911, 280,333 tons, \$6,022,210.71. It is

NEVADA, SHOWING COUNTY BOUNDARIES.

impossible to do this county justice in a limited paper of this nature. The Goldfield Consolidated Mines Co., here, is probably the richest gold producer of the world today. Its wonderful group of mines has much high-grade milling ore blocked out and a large acreage of undeveloped territory that doubtless contains untold wealth. Its new \$1,250,000 gold mill is now turning out bullion from 900 tons of ore per day, and the property has maintained a dividend rate of 50c. per share per quarter for a considerable time past. Other properties of exceptional promise in the Goldfield district are those of the Florence-Goldfield Mining Co., The Goldfield Combination Fraction Mining Co., The Mercer Mines Co., The Atlanta Mines Co., the Jumbo Extension Mining Co., and the C. O. D. Mines Co. The Diamondfield district has but recently come to the front with a find on the Goldfield-Belmont of vast importance. This is giving new life to the district. The Rawhide district has many promising prospects. In the Silver Peak district the Pittsburg-Silver Peak Mining Co. is maintaining a large, steady, and profitable production of low-grade milling ore, of which there is an immense quantity in sight. The Gold Mountain district is particularly worthy of mention as a highly mineralized

section and will doubtless be heard from in a substantial manner before a great while.

Eureka County.—Eureka county produced, during the year 1909, 102,622 tons of ore of a gross value of \$815,098.96; during 1910 the output was 29,578 tons, valued at \$181,146.53; for the first six months of 1911, 9832 tons, \$41,237.04. The great falling off in the production as shown by these figures is due to the complete demoralization of transportation facilities occasioned by an unprecedented series of cloudbursts and floods in the year 1909. The famous Richmond Consolidated and Eureka Consolidated properties, which were for a number of years the greatest lead-silver producing properties in the world, are now owned by the United States S. R. & M. Co., and several years ago this company expended over a million dollars in placing the mines on a producing basis. The figures for 1909 show the effects of this effort, and as soon as transportation is resumed considerable production may be expected, not only from this property, but many others. Active work is now in progress on the reconstruction of the railroad.

Humboldt County.—This county produced, during the year 1909, 8846 tons of ore, of a value of \$350,798.96; during 1910, 4260 tons, \$1,415,203.59; and during the first six months of 1911, 9166 tons, \$748,448.97. I want particularly to call attention to the almost unbelievable grade of the small quantity of ore extracted during 1910. Humboldt county, one of the largest counties in the State, has been but little prospected in comparison with others, but what has been done along these lines has been productive of most astounding results. In the National district are the mines of the National Mines Co., one of the richest producers of high-grade ore in the State. Certain slopes there are veritable treasure chambers, and development has been but fairly begun. There are a number of other excellent prospects in this district. Humboldt and Gold Run districts are worthy of especial mention and will show tangible results within a reasonable time. Three camps of wonderful richness have but recently been established in this county, Awakening, Barrett Springs, and Rexall. There is great activity in all, and the ore being extracted is extraordinarily rich in free gold. Particularly does this apply to the camp of Rexall, on the northern slope of Winnemucca mountain, where ore has been taken out that ran approximately 90% pure gold. This camp has been prospected to a depth of less than 100 ft., and, while the final outcome of any such mining venture is problematical, Rexall shows most flattering indications. A good deal of development is being done at both Awakening and Barrett Springs, and current reports indicate encouraging increases both in the size and richness of orebodies as depth is attained. In my opinion Humboldt county may reasonably be expected to prove a formidable rival for first place among the large producing counties of Nevada.

Lander County.—This county showed an ore production for the year 1909 of only 36½ tons, of a value of \$1892.05; during 1910 this was increased to 11,763 tons, valued at \$49,613.22; for the first six months of 1911 it produced 1688 tons, of an aggregate value of \$56,512.72. A very recent find of apparent magnitude has been made in Lander county 45 miles directly southwest of Austin, at what is known as the camp of Carroll. While no official returns for bullion tax purposes have as yet been made from this property, I am informed from what I consider reliable sources that three shipments have already been made, the lowest returns from which went \$270 to the ton. My last information was that a shaft approximately 4 by 8 ft. had been sunk to a depth of over 50 ft. on the deposit, and at several points therein the sides had been gouged out for a distance of 6 ft., and every inch of the surface exposed was in this same grade of ore. One of the original owners informed me, several weeks ago, that the property was under lease and bond to Salt Lake men for \$50,000, of which \$5000 was cash. A few days later I was told that the property had been taken over for cash. Lander county boasts a production during the early days of over \$36,000,000 in gold and silver, and its mineralized territory has scarcely been touched.

Lincoln County.—During the year 1909 Lincoln county produced 113,938 tons of ore valued at \$511,331.33; in 1910, only 760 tons, \$10,640; and for the first six months of 1911, 7326 tons, \$46,775.69. The same evil influence of cloudbursts and floods that proved temporarily so disastrous to Eureka county, figured largely in the decrease of Lincoln county's output; but, in addition, there must be added internal dissensions in the ranks of some of the larger operators. The flood damage in Lincoln county has been repaired, and indications point to an adjustment of the personal differences.

Lyon County.—This county produced, during 1909, 21,578 tons of ore, of an aggregate value of \$78,186.79; during 1910, 18,469 tons, valued at \$79,672.66; and during the first six months of 1911, tonnage not given, but of a value of \$18,848.66. The Lyon county product is largely in silver. There are large deposits of copper around Yerington and Mason. A standard-gauge road has been built into the district, and a smelter built near Wahuska. A large output of copper is anticipated.

Nye County.—This county produced, during 1909, 374,827 tons of ore, of an aggregate value of \$5,740,581.15; during 1910, 501,435 tons, \$9,051,441.27; and for the first

WESTERN NEVADA AND EASTERN CALIFORNIA.

six months of 1911, 363,401 tons, \$4,852,952.44. Nye county boasts the greatest number of producers of any county in the State. The Tonopah Mining Co. is, so far, the heaviest producer. The Tonopah Belmont Development Co. has found recently large new bodies of milling ore, and is a rival for first place. Other properties in the Tonopah district worthy of especial mention are the Montana-Tonopah, the Tonopah Midway, the Tonopah Extension, the McNamara, and the West End Consolidated. All of these are heavy producers. In the Manhattan district the maintenance of the present activity is bound to bring favorable results. The Round Mountain district is holding its enviable position as a producer of merit, largely through the efforts of the Round Mountain Mining Co., which is turning out high-grade gold ore. In the southern part of the county the Bullfrog, Rhyolite, Pioneer, and Johnnie districts offer a great field for exploration. The Mayflower, in the Pioneer district, and the Johnnie Mining & Milling Co. should be particularly mentioned.

Storey County.—This county for 1909 shows an ore tonnage of 83,048, valued at \$643,511.78; during 1910, 115,890 tons, \$548,866.16; and for the first six months of 1911, 43,515 tons, \$301,890.51. While the exciting times of the old Comstock days will probably never be revived, when that fabulously rich lode was pouring its king's ransom into the lap of an otherwise impoverished nation, yet every indication points to its taking a new lease on life and giving

up additional treasure with a bountiful hand. Recent important discoveries made in new territory have given marked impetus to prospecting operations. A considerable tonnage of commercially valuable ore is now being extracted by the Consolidated Virginia Mining Co., the Ophir Silver Mining Co., the Mexican Gold & Silver Mining Co., the Comstock Phoenix Mining Co., the Belcher Silver Mining Co., the Chollar Mining Co., the Crown Point Gold & Silver Mining Co., the Gould & Curry Mining Co., the Yellow Jacket Mining Co., and the Union Consolidated Mining Co. The Mexican, the Ophir, and the Phoenix have but recently reentered the dividend-paying class. The new mill recently erected by the Mexican has begun operation, and a large amount of development has resulted in opening considerable bodies of milling ore. The capacity of the new mill is estimated at 100 tons per day. Current reports credit the Nimis lease on the Gould & Curry property with a find of much importance. The Comstock district is now furnishing employment to approximately 1000 miners.

Washoe County.—This county produced, during 1909, 1200 tons of ore of a value of \$5000; during 1910, 543 tons, \$8510.62; and during the first six months of 1911, 623 tons, \$20,069.23. So far Washoe county has been a slight producer of metals of value. There are known to be large mineralized zones within her borders, but little prospecting has ever been done. The effect of honest persistent endeavor is evidenced to some degree by results recently attained on the property of the Nevada United Mines Co., some five miles in a northeasterly direction from Reno. What is known as the Arkell find on this property, after three years of unremitting labor without practical results, has at last brought it into what appears to be a just reward. The orebody has not as yet been opened sufficiently to warrant any broad assertions as to its size or value, but its general character and the surrounding conditions are most encouraging. The ore content is largely lead-silver, with a small proportion of galena, zinc, and gold.

White Pine County.—White Pine county produced, in 1909, 1,678,895 tons of ore (principally copper) of a value of \$7,114,354.19; during 1910, 2,407,462 tons, \$8,582,409.81; and during the first six months of 1911, 1,430,651 tons, \$4,326,529.49. This county, which during the late '60s and early '70s was the second largest silver-producing county in the State, and which for over twenty years lay dormant, is today one of the largest producers of copper in the world. The copper belt lies in the Robinson mining district close to the town of Ely, and it is here the famous Nevada Consolidated and Cumberland-Ely properties are found. Several years ago these properties were consolidated. The copper production from the Nevada Consolidated during 1909 was 57,964,477 lb., valued at over \$7,000,000, and in 1910 the production was 61,359,398 lb., valued at \$8,173,643. These figures represent 99.3% of the entire State's production of copper. During the years 1909 and 1910, it is understood, a curtailment agreement was in existence between all of the large copper companies, which had the effect of lessening the production of the Nevada Consolidated materially, but notwithstanding this agreement, this company handled close to 10,000 tons of ore daily, some of which carried but 0.8% copper, being the lowest-grade copper ever worked at a profit. Adjoining the Nevada Consolidated is the Giroux, the property of the Cole-Ryan interests, and which is credited with carrying the highest percentage of copper of any property in the Robinson district. The Giroux was purchased by its present owners several years ago, since which time development has been carried forward to place the mine on a large producing basis. The surface improvements on the Giroux are said to be the most modern and complete of any property in the United States. Notwithstanding several years' time and many millions of dollars have been expended on this property, it is not considered probable that the extraction of ore will be commenced before another year.

Douglas, Elko, Mineral, and Ormsby counties offer many excellent opportunities for development.

South Dakota Gold and Tin Mines

By R. L. DAUGHERTY

The output of the Black Hills mines from Nov. 1, 1910, to Nov. 1, 1911, was as below:

Company.	Tonnage.	Production	Men emp.
Homestake	1,510,302	\$5,875,000.00	2700
Mogul	135,000	481,709.00	210
Golden Reward	66,899	392,701.91	134
Wasp No. 2	148,700	295,907.75	75
Lundberg-Dorr-Wilson	21,018	75,754.00	22
New Reliance	8,300	31,492.62	40
Small mines, est.	55,110	379,950.00	793
Placers		83,000.00
Totals	1,945,329	\$7,625,506.28	3974

*The past twelve months have found the Homestake company in operation without interruption of any sort. The labor question is apparently settled, and there seems to be no difficulty in securing all the labor needed for the different branches of the company's operations. This company has nearly completed the construction of a magnificent electric-power plant on Spearfish creek, at a cost of about \$1,250,000, which will have a possible horsepower of 7500. Spearfish creek is taken up at a dam about nine miles from Spearfish and the water carried through concrete tunnels to the power buildings, which are built in the upper part of Spearfish.

The Homestake, Golden Reward, and other large companies enjoyed a prosperous year, as is shown by the tabulated output. The year was marked by the beginning of dredging operations at Mystic, which has attracted renewed attention to the placers of the Black Hills. Prospecting has been active throughout the Hills, and the foundations are being laid for a renewed activity in mining gold and silver throughout the region.

Much is expected from the new smelter that is being erected at Galena by the Black Hills Smelting Works. The plant will have a daily capacity of 300 tons of charge, with pyritic smelting. The Burlington company has extended its narrow-gauge track to the plant. The management expects to be able to handle profitably ore that carries but \$4 per ton in gold. One of the principal contributors of ore will be the Gilt Edge-Maid mine, which is near by. The mine has been undergoing extensive preparations for a large tonnage production. The ore will be hauled over the Burlington track to a new concentrating mill which the new Gilt Edge-Maid company has built near the smelter. The plant will be able to handle 250 tons daily of raw ore, which will be concentrated to about 50 tons, and this will furnish the flux for the smelter. There are a number of mines in the Galena district within a radius of three miles, which will be given an opportunity to furnish ore for the smelter.

Progress has been made in the development of the tin resources of the Hills this past year. The Tinton Tin Co. has kept a small force of men at work most of the time in the mine, but no mill-run has been made. In December 1910 the company shipped 86,000 lb. of black tin to Liverpool, England, which made 48,250 lb. of metallic tin. This was sold at 37c. per lb., or \$13,027.50. The company has a considerable amount of tin concentrate on hand. There is apparently an abundance of tin-bearing ore, and the milling should not be a difficult metallurgical problem.

One new company has been organized to operate in the Tinton district during the year. It is known as the Scotland Mining Co. It has purchased the A. J. Johnson ground, which carries an extension of the Tinton tin veins to the north. Active development of these tin veins on the property is now in progress. A number of well known mining engineers have examined and made reports on these tin properties the past few months, and it is known that some very favorable findings were made, which will undoubtedly mean more activity in this camp during the coming year.

*Abstract from annual report of State Mine Inspector.

Colorado Metallurgical Progress

By P. H. ARGALL

In reviewing the metallurgical processes in operation in Colorado at the close of the year 1909, I emphasized the following changes then taking place: (1) The decline of the smelting industry, due to the scarcity of high-grade ore; (2) the decadence of the chlorination process as a factor in the treatment of Cripple Creek ores; (3) the rejuvenation of the cyanidation process. At the close of the year 1911 the corresponding situation is: (1) The smelting industry is about holding its own at the 1909 tonnage; (2) the chlorination process is no longer a factor in the treatment of Cripple Creek ores, the Standard mill, handling about 8000 tons per month, having closed December 1; (3) the cyanidation process now occupies first place, with the Golden Cycle and Portland mills at Colorado City and Stratton's Independence and the new Portland mills at Victor. The Golden Cycle has treated an average of 25,000 tons per month throughout the year, the Portland 6000 or more, the Stratton's Independence 8000 to 10,000, and the new Portland 6000 to 10,000 tons. Both the Portland and the Standard plants have been re-working the tailing from old chlorination mills by the cyanidation process at substantial profits, and the Portland is now eliminating chlorination and changing the entire mill to cyanidation.

CRIPPLE CREEK

The past two years have been active ones in the metallurgy of Cripple Creek ores. The valley plants still treat 80% of the ores produced, though division according to

lower-grade ore, and treatment methods must be devised to meet this condition. The valley plants, with a dollar a ton freight for a 30-mile down-hill haul, have about reached their limit in the matter of freight and treatment charges, as a comparison of the following tables will show:

FREIGHT AND TREATMENT

1909			1911		
Oz. Au		Per ton	Oz. Au		Per ton
Up to 1/2	\$4.00	Up to 1/2	\$4.00
1/2 to 3/4	5.25	1/2 to 3/4	4.50
3/4 to 1	6.00	3/4 to 1	5.00
1 to 1 1/4	6.50	1 to 1 1/4	5.50
1 1/4 to 1 1/2	7.00	1 1/4 to 1 1/2	6.00
1 1/2 to 2	7.50	1 1/2 to 2	6.50
2 to 3	8.50	2 to 3	7.00
3 to 5	8.75	3 to 5	8.00

That this scaled rate, at best, no more than covers expenses on the lower grades is borne out by the following significant statement from the last annual report of the United States Refining & Reduction Co., operating the Standard mill: "An increase in tonnage was not possible, nor was the management able to obtain treatment charges giving any material profit over and above actual expenses."

Of the mills in the district, the Jo Dandy, Wild Horse, and Anaconda are simple cyanidation plants, and having oxidized ores to deal with, present nothing new. Stratton's Independence and the new Portland, being designed to treat low-grade sulpho-tellurides, mark the new metallurgical strides, hence more or less detailed accounts of these two mills will be presented.

Stratton's Independence.—The process, or combination

MILLS FOR TREATING CRIPPLE CREEK ORE

Name.	Tons capacity.	Process.	Remarks.

Homestake	50	"	"

processes shows a change. Of the ore sent to the valley plants in 1909, about 50% was treated by chlorination; in 1911 fully 70% has been cyanided at the Golden Cycle mill. The small cyanidation plants in Cripple Creek district proper, those designed to treat oxidized ores, have not accomplished much. The Wild Horse was the only one in fairly continuous operation throughout the two years. The Wishbone roast-cyanide mill closed down early in 1910 and was destroyed by fire August 13, 1910. The Trilby roast-cyanide mill has not been operated at all during the period, and the Anaconda has been but lately re-started. The Kavanagh mill on the Jo Dandy, and the Ajax Clancy-process mill are new.

The big feature of the two years in the Cripple Creek district has been the increase in milling of low-grade ore. Each year the district is producing a larger tonnage of

of processes, elaborated by Philip Argall in the spring of 1907, and laid before and approved by the directors of Stratton's Independence, Ltd., in June of that year, provided for:

1. Crushing the ore in cyanide solution instead of water in order that the cyanide should begin dissolving gold from the moment that fine crushing began.
2. Removing the rebellious tellurides as completely as possible by a careful concentration conducted alike on sand and slime.
3. Leaching the sand in ordinary tanks to effect a further extraction and to wash out the remaining traces of cyanidation.
4. Treating the slime by air-agitation and bromo-cyanide or other oxidizers as and when required. (A long and thorough series of full working tests has since established

ough series of tests demonstrated bromo-cyanide as the best solvent, though even bromo-cyanide is at times useless, and at all times requires the most careful chemical application.)

In Mr. Argall's report of April 19, 1907, made after the completion of his tests on the dump ore, he showed that an extraction of 70% could be obtained at a total cost of \$1.52 per ton treated, on a basis of milling 10,000 tons

triet, the new Portland, began operations in June 1910 with a secret process, of which details have not yet been made public. After various changes during a 'trying-out' period, the mill settled down to steady work. The process now used includes crushing and concentrating in cyanide solution, discarding the sand after concentration and water-washing, air-agitation of the slime aided by a halogen eya-

STRATTON'S INDEPENDENCE MILL, WITH AJAX IN BACKGROUND.

NEW PORTLAND MILL, CRIPPLE CREEK, COLORADO.

per month. This is not a high recovery, but anyone who has struggled with Cripple Creek sulpho-telluride ore will admit it is quite a feat to obtain 70% from \$2.75 unroasted ore, yet, as a matter of fact, actual milling results have bettered the estimates made before the plant was designed, full details of which are given in *The Mining Magazine* for November 1911.

New Portland.—The second important mill of the dis-

nide when necessary. The concentrate produced in this mill is shipped to the Colorado City plant of the Portland company for roasting and cyanidation; the cyanide precipitate is also worked up into bars at the same plant. The costs and the recovery are closely guarded; in the annual report of the company receipts at the mine and the two mills are lumped together in one item, "cash receipts from operation of mine and mills." The local

papers, however, under date of October 19, 1911, give the following: "In the last three months, ending September 30, 29,599 tons were treated, resulting in a profit of \$33,110.78, averaging better than a dollar a ton for the owners." The Portland is now a splendid mill, well managed, successfully operated, and will proceed in time to greater successes, but not greater than the expenditure deserves, or than all metallurgists wish the able and energetic staff.

Ajax.—The big experiment of the year, the Ajax Clancy-process mill, started early in November and is still undergoing alterations and adjustments. The Clancy process is a radical departure from standard practice on Cripple Creek low-grade ores, in that concentration is to be eliminated and the recovery to be made by straight chemical methods aided by electricity. This is the most recent Clancy process, and its merits or demerits remain to be seen. Mechanically the mill is rather complicated, which is to be regretted, since a new process is to be tried, but this apparently does not dampen the enthusiasm of A. W. Warwick, the chief metallurgist, who has already predicted the chemical consumption at 12c. per ton and the total cost per ton at \$1.20. The formal beginning of continuous milling operations at the Ajax mill is awaited with expectant interest. Everyone in the district wishes a success may be scored by the new process, fully up to the claims made by Mr. Warwick, as in that event a notable advance will be marked in Cripple Creek metallurgy. None of the methods now in use is perfect, and the profession will welcome any improvement to increase the profit in milling low-grade ore. One of the cyanidation-concentration mills producing a high-grade smelter product has got the cost of treating the concentrate down to 10c. per ton milled; this, plus the small cost of concentrating, is an expense the Clancy process seeks to avoid, and to do so it may be necessary to crush the ore to pass 150 or possibly 200-mesh screen aperture. Hence, unless much higher extractions are obtained, the gain is not worth the candle.

Isabella.—An attempt was made during the year to work over the tailing accumulation of the Isabella mill, but without success, the plant now being idle.

Summary.—Taking the district as a whole, the following general summary may be made. There is an ever increasing quantity of low-grade ore being produced which will lead to the building of many more mills in the district. From present indications the method in use at the Independence mill is the most likely to be followed, due to its cheapness and ease of application. The valley mills will soon suffer a decrease in ore-supply due to home milling, and to the fact that concentrate, to be produced in the low-grade mills, is a smelter product. A further point to be noted in the cyanidation mills is that the mechanical means employed have about reached their highest stage of usefulness, and that any further progress must be along chemical lines.

LEADVILLE

Sulphide ores form the bulk of Leadville's production, the chief ore being iron pyrite carrying a little gold and silver with frequently some lead and copper. The ores are sent direct to the Colorado smelters. The second largest tonnage is made up of the mixed sulphide ores, that is, zincblende, pyrite, and galena. The higher-grade zinc sulphide ore is shipped direct to the zinc smelters at points in Kansas and Oklahoma, while the lower-grade and mixed sulphide is sent to the concentration plants at Cañon City, Pueblo, and Denver. Of the oxidized ores, iron oxide, carrying about 10% manganese, forms the greatest tonnage, with zinc oxide ores coming next in point of production. Lead oxide ores proper now form but a small proportion of the total output. Iron and lead oxide ores are smelted locally, while the oxidized zinc ores are sent to the zinc smelters for treatment. Silicious sulphide ores, carrying gold, silver, and copper are now being mined in greater quantity, and this material finds a ready market at the Colorado smelters.

The Arkansas Valley smelter at Leadville has been in continuous operation throughout the year treating about 600 tons per day in four furnaces. This plant is equipped

with eight blast-furnaces, and is therefore running on approximately one-half its normal capacity, as indeed is the case with most of the Colorado smelters. Practically the only mechanical improvement effected at this smelter during the year has been the addition of several sintering pots to increase the roasting capacity of the Huntington-Heberlein plant. This added roasting capacity was made necessary by the constant increase in the proportion of sulphide ores coming to the plant. In order to handle the silicious ores carrying a low sulphur content, Dwight-Lloyd sintering machines are soon to be installed.

The milling of Leadville's low-grade mixed sulphide ores has never been locally conducted with any marked degree of success, and, of the various mills and concentration plants erected in the district, not one is now in operation. The failure of these mills may be attributed both to the complex nature of the crude ore and to the high cost of operation. The past year witnessed the closing of the Rowe mill, of the American Zinc Extraction Co., owing, it is said, to the lack of a sufficient supply of suitable ore to keep it in successful operation. This mill was erected to treat low-grade iron-zinc sulphides and had been in continuous operation since 1905. As originally designed, the ore was crushed and sampled when dried and further reduced to pass a 0.043-in. screen aperture, after which it was fed to International separators, where a magnetic separation of the blende and iron was effected. With a change in the nature of the ore received, the operation of these separators upon the raw ore did not prove satisfactory. They were consequently eliminated and the process was altered to include a magnetic roast in White-Howell furnaces, followed by cooling prior to magnetic separation on Cleveland-Knowles machines. These machines picked up the magnetic iron, the zinc, with its associated minerals and gangue, passing as zinc product. While running on iron-zinc sulphide ore the last described method of treatment was profitable, and was later extended to handle ores containing some galena and a more highly silicious gangue. This was accomplished by the addition of a wet-concentration plant, where the product from the Cleveland-Knowles separators was passed over tables obtaining a resultant product of lead sulphide heading, a zinc sulphide middling, and leaving the gangue to pass off in the tailing. It was at first found difficult to obtain a clean separation between the galena and blende, while considerable zinc losses occurred in slime, but these difficulties were finally, in a large measure, overcome. During the life of the mill it had done much toward solving the problem of concentrating the low-grade mixed sulphide ores of Leadville, and its keen competition in bidding for an ore supply resulted in materially advancing the price paid the miner for such ores. The low-grade iron-zinc and zinc-lead sulphides are now being shipped to the Cañon City mill, of the Empire Zinc Co., and to the plant of the Western Chemical Manufacturing Co. at Denver. The crude ore does, however, receive some preliminary preparation for the market, as hand sorting has been adopted at most of the mines with highly satisfactory results. The common practice is to pick out the silver-bearing pyrite and galena, and also the higher-grade zincblende, which separate products are then shipped direct to the various smelters, leaving the bulk of the mixed sulphide to be sent to the zinc concentration mills as noted above.

The production of oxidized zinc ores is now an important feature of Leadville's mining industry. Although the valuable nature of these ores was not recognized until late in 1910, so rapid has been their development that shipments of zinc carbonate ore have already reached a monthly output of some 12,000 tons. This tonnage is sent direct to the Eastern zinc smelters and shipments are limited to ores containing an average of 30% zinc. The general schedule upon which these ores are purchased has been extended to all producers alike, and is as follows: \$15.60 per ton, dry weight, f.o.b. standard-gauge cars at Leadville, Colorado, for ores containing 35% zinc, when spelter sells at \$5.50 per hundred pounds St. Louis; the variation per unit to be at the rate of \$2 per unit above 35% zinc and down to 30% zinc, and at the rate of 90c. per unit below 30% zinc; as

the spelter market varies from \$5.50 per hundred pounds, the price per ton of ore to be changed for each 1c. variation in spelter per hundred pounds. Extensive deposits of low-grade zinc carbonate ores have also been developed; that is, material averaging 23% zinc, which at present is not a marketable product. Several trial shipments of this material, in lots of about 500 tons each, have been sent to the various zinc smelters and oxide plants for testing purposes. The results obtained in these experiments were evidently unsatisfactory, as no demand for the low-grade ore has yet been created. It would therefore appear that these ores cannot be profitably smelted direct according to existing methods of treatment. The problem then is to bring these ores up to the standard required by present market conditions, and numerous metallurgists are now in the field working toward the successful solution of this problem.

SALIDA

The Ohio & Colorado Smelting & Refining Co. at this place is running two blast-furnaces and treating an average of 9000 tons of ore per month, drawing its ore supply from Leadville and the San Juan region. Many mechanical improvements have been introduced during the past two years, and this plant is now regarded as one of the most up to date in Colorado. The chief improvements have been made in the roasting department, where hand-worked reverberatory furnaces have been eliminated and three Godfrey mechanical roasters installed. These latter have a daily capacity of 30 tons each and reduce the raw sulphide ores to about 20% sulphur. This partly roasted product is fed to four Dwight-Lloyd sintering machines, where the roast is completed. This plant was one of the first to adopt the Dwight-Lloyd machines, and it was largely through the efforts of the management here that many of the early mechanical defects were corrected and the whole process worked out to a successful conclusion. An electric haulage system for handling the slag has just been installed.

PUEBLO

The Pueblo smelter has increased its Huntington-Heberlein plant somewhat to accommodate the increased tonnage of concentrate received, and has been operated at a little better than one-half capacity throughout the year. The zinc smelter has been run at full capacity, with nothing new along metallurgical lines to report. The steel works has had three blast-furnaces and twelve open-hearth furnaces in operation throughout the year. The prices on all products except rails have been much lower than in years, yet a substantial gain is shown in the net earnings, speaking well for the metallurgists in charge. The principal ore supply is in Wyoming, a heavy tonnage also comes from New Mexico.

DENVER

The Globe smelter has operated at one-half capacity this year, the only changes noted being the contemplated installation of Dwight-Lloyd machines. The Argo smelter has passed into history. The past year witnessed the working over of the dump with considerable profit to the lessees. The Modern smelter, as predicted two years ago, is extinct, having been literally smothered in its own blue-dust, and leaving certain misguided ones \$700,000 out.

GOLDEN

The plant of the North American Smelting Co. at Golden has run at full capacity throughout the year on ores from Georgetown and Idaho Springs.

IDAHO SPRINGS

The Hudson Reduction Co. at this place has during the year remodeled the old Hudson concentrator and applied electro-amalgamation and cyanidation. The ore is stamped, run over amalgamating plates, and further amalgamation accomplished in tank electro-amalgamators. The resulting pulp is concentrated on Card and Willey tables, followed by agitation in cyanide solution, the concentrate being shipped to the smelters. Excellent results are said to have been obtained.

SAN JUAN

The famous mills of this district, the Liberty Bell, Camp

Bird, Smuggler, and others, have been operating steadily. Certain minor improvements and changes making for lower costs have been introduced, and the general practice is up to date and thorough.

GENERAL SUMMARY

In conclusion, the coming year is apt to witness considerable metallurgical activity. The crying need is for some method of handling the low-grade zinc ores of Leadville, and this problem I expect to see solved in 1912. The smelters face a chronic decrease of high-grade silicious ores and a constantly increasing production of concentrate; indeed, this shortage of silica may become a vital problem during the coming year. Cripple Creek will witness the trial of the Clancy process, and many contemplated mills are being held up until the results of this trial are known. The United States Reduction & Refining Co. is turning its attention to the cyaniding of its various tailing dumps; the one at the Union Plant at Florence is now being so treated. On Friday, November 10, a great flow of water came into the Roosevelt deep drainage tunnel at Cripple Creek, marking practically the completion of this enterprise. Deep mining will therefore be possible early in 1912, with a greater number of men employed and renewed activity in both mining and metallurgy.

Eastern Oregon

By OUR SPECIAL CORRESPONDENT

During 1911 there was a pronounced revival of mining operations in eastern Oregon, which applies principally to Baker and Grant counties, for which Baker, Sumpter, and Granite are centres. One feature of the year's progress was the renewal of operations on the North Pole mine, at Bourne. This property was operated successfully for ten years by Baring Brothers through E. Melzer as manager. After a period of idleness lasting two years, it has been reopened by a Portland company under a bond and lease. It is a gold mine, the veins of ore in which are in a zone of slate. On the same belt is the Columbia mine, which has been operated steadily for fifteen years. The property is well equipped, the mill including stamps, amalgamation and cyanidation departments. During the period named there has been no change in the management, which has been in the hands of Frank S. Baillie. The Goleconda, situated on the same zone as the Columbia and North Pole, was started up by Spokane operators after having been closed a number of years. The Red Boy, a big producer ten years ago, is situated near Granite. It passed through a period of idleness, but within the past two years has been explored and developed extensively, whereby its prospects have been much improved. The Red Boy is well equipped with air-compressor, hoist, and mill, and is supplied with water-power. The operations in the Greenhorn district have been marked by good progress, several mines being at work on a small scale. The Highland mine, situated between the old Baisley-Elkhorn and the North Pole mines, has been under development during the past three years. Some ore of good grade has been shipped, and a large tonnage of ore of milling grade has been exposed; the Highland G. M. Co. is now erecting a mill for jig and table concentration, the valuable metals consisting of gold and silver associated with iron pyrite. Tests show a recovery of 85% by this method. The Rainbow mine, situated in Mormon basin, was developed and put on a paying basis within the past eight years by the Commercial M. Co., which sold the property about ten months ago to the United States S. R. & M. Co. Since the consummation of the purchase the mine and mill have been in charge of the exploration department of the latter company. The Humboldt mine, in the vicinity of the Rainbow, has been in course of development during the year, with encouraging results. The Dixie Meadows mine and mill, situated at Prairie City and controlled by New York men, have been in operation during the year. The ore consists of gold-bearing quartz, containing sulphides; the milling method consists of stamp crushing, amalgamation, and concentration. Experiments are being made with the view to cyaniding the tailing.

Arizona

By C. F. TOLMAN, Jr.

In reviewing mining conditions in Arizona for the year 1910, some indirect benefits accruing from the cautious attitude of capital toward mining ventures were mentioned, and attention was called to the decline in wild-catting, and the forced advances in mining and metallurgy. These tendencies have been still more in evidence during the year just finished, and those companies that have been able to weather the financial storms of the past few years are reconstructing their plants, developing more economical methods of mining, or combining with adjacent properties; the last for economically working the deposits, rather than with a view to stock manipulation. The list of companies building or rebuilding reduction plants includes all but two of the important copper producers. In addition to the great Cananea plant just rebuilt, which lies south of the Arizona boundary line, the new concentrator at Miami has been finished, its last unit having been set to work. The concentrator and new smelter at Ray are nearing completion. A 5000-ton mill for the Inspiration M. Co. is being planned, as well as a reduction plant for the Ray Central. The construction of an entirely new plant has been authorized by the Arizona Copper Co. at Morenci, and the reconstruction of the Calumet & Arizona plant at Douglas has been begun. Finally the United Verde has decided to build a new smelter in the valley below the mine. All of this reconstruction work is under the charge of three noted engineers, L. D. Ricketts, H. Kenyon Burch, and C. H. Repath. After all the experimental work on the ores at the mines, and with the advantage of having the results of the concentration of similar ores in Utah and elsewhere, the 65 to 70% saving at Ray and the reported 75% saving at Miami is far from cause for congratulation when the value of the lost product is considered. The query will not down: 'Has not wet-concentration for the chalcocite ores been thoroughly tried and been found wanting?'

The work of the past year at Ray and Miami has taught its lessons regarding the saving of ores, and much more will be learned next year. The combination of properties for the economical working of the deposit is much more difficult to effect than the solution of engineering problems of mining and metallurgy. During the past year preliminary steps have been taken for such combination, and much will probably be accomplished along this line this year. Where claims interlock and caving stopes in one mine injure the neighbor, as at Morenci, the demand for combination is evident, but as far as known, no combinations are contemplated in this district. The expense of pumping and the depth to the sulphide ores, demand the combination of all companies on the Old Dominion and parallel lodes at Globe. The combination of two of these (the Arizona Commercial and the Superior & Boston) is practically consummated. At Ray, the Hercules and the Ray Central are planning to combine, possibly to make the task of swallowing both easier for the Ray Consolidated. The Miami-Keystone-Inspiration-Live Oak combination, so much discussed, was a logical one, and would have covered all that has been developed of the great ore zone, with approximately 60,000,000 tons of proved ore. It would have been at some loss, however, of the most important stimulus for advanced engineering work—competition of adjacent mines working under the same conditions.

Little has been made public during the past year of technical and scientific interest regarding the developments in the older camps. At Bisbee the deeper sulphide orebodies developed by the Calumet & Arizona company are of interest and should be described. The purchase by the Copper Queen of properties covering the 'ore trough' toward the southeast beyond any of the workings, is interesting. At Globe, the satisfactory results of further exploration in the Old Dominion are reported. The Miami-Inspiration ore zone has been developed actively as noted above, and the discovery of ore on the Southwest Miami is interesting in that it extends the zone in that direction. The great

depth at which the secondary sulphides are found at this end of the orebody (1000 to 1400 ft.) is the result of peculiar structural relations, and of past topographies. These will probably be discussed in F. L. Ransome's report on the re-survey of the district. At Ray the interest centres in reduction plants and mining methods, and it is to be hoped that the results of the experiments along both lines will be made public.

The paralysis that has affected the mining operations of all but the larger companies has extended to prospecting, so that new finds of importance are hardly to be expected. There seems, however, but little chance of finding a new disseminated deposit of anything like the size or value of the Ray orebodies or the Miami-Inspiration ore zone. The Bagdad Copper Co., operating north of Hillsdale in Yavapai county, is reported to have developed a 2% disseminated copper deposit containing five to six million tons of ore. The disseminated deposits in the neighborhood of Silverbell, Pima county, have been developed to a considerable extent, but the results have not been made public. It may be stated, however, that the ore is concentrated along silicified fissure zones in the porphyry and granite, and therefore lacks the continuity of the Ray orebody. The reported tonnage and the value of ore given out by the Copper Creek company in the Galiluro mountains, Pinal county, would receive more attention if vouched for by an engineer of standing. This property is reported to have been taken over by a French company. The famous Ajo properties have been bonded by the Calumet & Arizona. The possibility of a disseminated deposit here has been recognized for a number of years, and an attempt to drill was made by engineers connected with the Ray Con., but it was abandoned on account of the difficulty of churn-drilling. The development on the large number of copper prospects has been cut down in most cases to the assessment work necessary to hold the claims.

The Copper Queen Consolidated Mining Co. is busily pushing development on claims it has bonded in the Old Hat district, 30 miles northeast of Tucson. The claims cover a part of the extensive garnet zones of the Marble Peak contact, and the result of the work is reported to have been satisfactory. A story has been told about the bonding of these claims that has a moral, even though it cannot be vouched for as authentic. It was said that these properties are the first that have been offered the Copper Queen at a reasonable figure, and, to encourage this unusual attitude of mind, the company took the bond and unexpectedly found ore. Failures are seldom reported in a yearly review, but they are as much history as the successes, and often as instructive. The closing down of the Clara Consolidated smelter and properties was not unexpected to those who had some acquaintance with the project. The shut-down at Tombstone has been a disappointment to all mining men on account of the historical association of the old camp and admiration for the courage of the Development Company of America in going against such odds. The shut-down at Imperial is generally considered to be only temporary, in spite of foreclosure proceedings. The only happening in the 'high financing' of Arizona mines that has met with general censure is the turning over of the Ray smelter to the A. S. & R. Co., the feeling being that the Ray company would have done better to keep for itself the profit on smelting its ore.

There is little new in regard to the development of gold, silver, lead, or zinc deposits. The unexpected size of the coalfields of northern Arizona, as appears from the recent reports of the U. S. Geological Survey, would attract more attention were there some satisfactory way of getting hold of large enough holdings to justify the development of these isolated deposits. Oil development is active throughout Arizona, and while oil indications have been encountered during the drilling, no commercial quantities of oil have as yet been developed. It is to be hoped that the undisturbed Tertiary formations of the desert valleys will be found to be oil bearing in places and that productive fields may be developed.

Montana

Copper is still the most important metal produced in Montana. In 1911 the production is estimated at close to 275,000,000 lb., including the output of all the independent properties. The production of the smelters of the Anaconda company, with December output estimated, totals 258,152,000 lb., and that of the East Butte smelter, with the months of November and December estimated, amounts to 12,586,699 lb., making the total production of the Washoe, Great Falls, and East Butte smelters 270,738,699 lb. In the production of the Anaconda company is included the output of the North Butte and Tuolumne companies, as both concerns have their ore treated at the Washoe smelter, while in the East Butte figures are included the output of the Butte-Alex Scott, which has been shipping about two cars per week. The production of the North Butte for the year will average about 2,000,000 lb. per month, and that of the Tuolumne 500,000 lb. per month. In connection with the production of copper there is an important output of silver from the Butte mines, and some gold. The large number of gold-silver mines proper are in counties other than Silverbow, as will be seen by the review of the State by counties, by Mr. McGee.

Gold-Silver Mines of Montana

By GEORGE T. MCGEE

In this review the gold and silver production given is for eleven months, ended November 30, 1911. The figures include the output of both placer and quartz mines, but only the amount purchased at the U. S. Assay Office at Helena has been taken into account. The figures are misleading, in that they do not indicate the value of ore shipped to smelters, or metals sold in other markets, and final totals for the year will be much larger. The exact figures given below may appear absurd, therefore, but it should be remembered that these represent an exact record of a part of the total production.

Beaverhead.—The county contains the famous old district of Bannock. Operations have been confined to the work of lessees and prospectors. Base ores and long hauls to the railroad are serious problems. Gold and silver production, \$212.98.

Broadwater.—Winston and Radersburg have shown the most activity, and probably the latter has seen more real money put into new companies and real development work than any district in the State—Butte always excepted. A depth of 700 ft. on the dip of the vein has been reached, and the character of the ore remains practically unchanged. It is a heavy iron sulphide, most suitable for smelting. The twelve-mile wagon haul to the Northern Pacific railroad would undoubtedly be done away with, were it not for a railroad bridge across the Missouri river, which would be necessary for a spur to the mines, and that may be built soon. A large amount of gold and silver comes from the Keating and other mines in the form of smelting ore. The gold and silver received at Helena, amounting to \$7439.57 in 1911, represents the smaller mines.

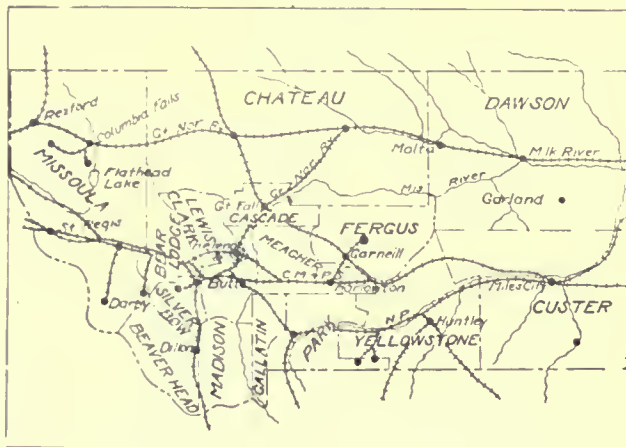

Carbon.—Bordering the northwest corner of Wyoming. Carbon county has extensive coalfields, which, although they have produced for years, are now undergoing especially rapid development. The metal miner in Montana is apt to overlook the commercial and economical importance of the coal deposits. The county's production of coal for the year will approximate 1,200,000 short tons, requiring the labor of 2000 men, and having a value of \$2,100,000 at the mines.

Cascade.—A large area is most excellent agricultural land, in the midst of which is Great Falls. Nelhart, the famous silver district of the county, is still a shipper of lead silver ore, and the operators are continuing work and hoping for better prices. The old Queen of the Hills shaft was unwatered last summer by one of the largest and strongest operating companies in the country, and there was a considerable holding of breath for a while—until the shaft was allowed to fill again. Cascade county is rich in coal,

and the mines employ modern equipment, including coal-cutting machinery. The 1911 estimated output, from the 1000 men employed, is 1,000,000 tons, valued at \$2,000,000.

Chouteau.—The Little Rockies in the southeastern corner of the county have continued to pour forth their gold, and exploration has been carried on by both old and new companies. The district suffers from being fifty miles from the railroad. Gold and silver production, \$370,061.11.

Deer Lodge.—Cable, Georgetown, and neighboring districts, welcomed the news announced late in the fall, that the Anaconda Copper Mining Co. had acquired the Southern Cross mine and would at once commence the extension of the Butte, Anaconda & Pacific railroad in Georgetown. The iron oxide ores of the district, difficult to treat locally, will be welcome at the Washoe smelter, and their production will be greatly stimulated by cheap transportation. Gold and silver production, \$16,229.71.

MONTANA.

Fergus.—The Kendall mine continued to operate profitably at Kendall, and lessees have operated successfully the Gold Reef mine at Gilt Edge and the Maginnis and Cumberland mines at Maiden, in the Judith mountains. A new company commenced operations on the New Year mine. Cone Butte and Ford Creek districts are developing slowly. The county has been an important coal producer, but the Roundup coal district, which will show approximate output for the year of 650,000 tons of sub-bituminous coal, is now in the newly created Musselshell county. The coming of the C. M. & St. P. railroad four years ago, led to the discovery of the Roundup mines, and they are developing by leaps and bounds. Gold and silver production, \$262,964.44.

Granite.—Many years ago, the Hope mine at Philipsburg and the Granite-Bimetallie at Granite began the production of rich silver ores, and they are still at it. New work is under way, especially in the southern part of the county, which will be reached by the extension of the B. A. & P. railway. Gold and silver production, \$11,439.18.

Jefferson.—After the old placer days, some of the first quartz mining and smelting done in the State was in the Corbin and Wickes districts. The county is a steady shipper of lead-silver ores, the principal output coming from the Elkhorn mine. Three well financed copper companies are developing properties, which are not yet heavy shippers. Gold and silver production, \$10,180.83.

Lewis and Clark.—Many mining men expect to see the Marysville district at the front once more. Thomas Cruse has been operating steadily the Bald Mountain mine, and prospecting has been active over the entire district. The long-drawn-out differences between the Drum Lammion and St. Louis companies are practically ended, and the latter company started operations in both properties. On the Missouri river, east of Helena, at the mouth of Magpie gulch, a modern electric, deep digging bucket-dredge, with a capacity of 120,000 cu. yd. of gravel per month, was started early in the summer, with every prospect of success. At Helena, the Northwestern Metals Co. has been quietly building a 100-ton plant for the electro-chemical extraction of metals from ores, by the Burwell process. The aim will be to treat ores carrying zinc, lead, iron,

silver, and gold, for which there is a poor market, and on which the smelting charge is often prohibitive. Gold and silver production, \$170,455.74.

Lincoln.—The Snowshoe mine, 20 miles south of Libby, began shipment of lead ore and started a 5000-ft. adit for prospecting purposes. Placer ground of great promise was sampled, and development work was general over the county. Gold and silver production, \$1745.79.

Madison.—Prospecting went on steadily, and a successful producer has been developed in the Winetka mine, 4 miles above Virginia City, on Alder gulch. The work of the Conrey and Poor Farm Placer Mining companies is discussed in a supplementary article. In the Pony district, the Clipper and Strawberry mines have been steady producers, both worked under lease. Tungsten ore was found in the same district. Gold and silver production, \$547,983.80.

Meagher.—A number of copper properties are being developed in the county, and better railroad facilities would hasten work materially. Gold and silver production, \$101.46.

Missoula.—The northeast slope of the Bitter Root mountains, running off to the northwest, to within sight of the Coeur d'Alene country, is included for many miles in Missoula county, and promising prospects are showing up well. Gold and silver production, \$30,982.92.

Park.—Here is another large area of coal land, which will produce 100,000 tons of coal for 1911. Gold and silver production, \$1505.22.

Powell.—Some of the old-time placers were in this county, and deeper gravels are yet to be mined. Development is slow but steady. Gold and silver production, \$30,584.46.

Ravalli.—This county is credited with a gold and silver production for the year of \$1210.44.

Sanders.—That portion of Montana immediately east of the famous Burke district of the Coeur d'Alene is included in Sanders county, and development there has been quite active, but production is still small.

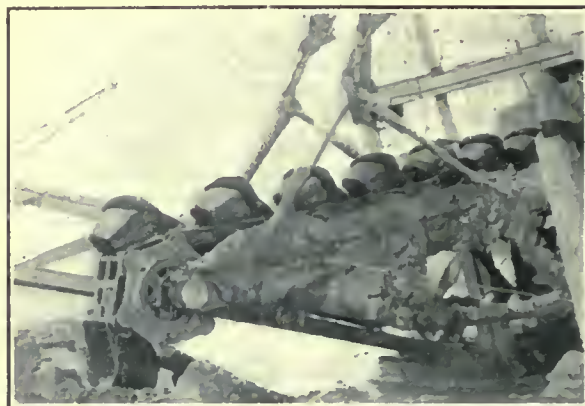

Silverbow.—The greatest mining activity of the State is centred in Butte. During the year, the first of the huge steam hoists has been rebuilt to use compressed air, delivered from a central plant and reheated at the shaft where used. This central plant is electrically operated, and in connection an automatic hydraulic auxiliary storage supply is maintained, to tide over any short breakdowns of the electric power lines. Since the output of the several power plants situated along the Missouri river, the Big Hole, and the Madison, can be thrown together, the likelihood of a complete breakdown is remote. Within the year the Washoe sampler, for handling custom ores, as well as those from the Anaconda company's mines, was rebuilt with a greater capacity. The East Butte company, operating the old Pittsmonst smelter, added a new dust-chamber and stack. At the Washoe smelter, new slime-treatment plants have been built. Everywhere the additions and improvements are of a substantial character. The coming year will witness the construction of two and possibly three concentrators. The Butte & Superior company has already commenced work on its mill, which will have a capacity of 500 tons per day and will be one of the most modern in the country. The Butte Central Copper Co., operating the Ophir mine, has made preliminary arrangements for the erection of a concentrator, and work is to be commenced in the early spring. The Butte & Superior mill is to be ready for operation by June 1, while that of the Butte Central will be completed early in the summer. W. A. Clark has announced his intention of building a concentrator for the treatment of his zinc ore from the Elm Orlu mine, but since that announcement was made a rumor has been in circulation that he may take possession of the Basin Reduction Works' mill, the lease on which to the Butte & Superior company expires on July 1.

Summary.—Montana metal production will be a large factor in the markets of the world for a long time. Important discoveries of phosphate rock have been made during the year in Beaverhead, Madison, and Silverbow counties, 30 miles south of Butte, and there is every indication of a growing non-metallic and metallic mineral industry.

Gold-Dredging at Ruby, Montana

By HENNEN JENNINGS

*The operations of the Conrey Placer Mining Co. and those of the Poor Farm Placer Co., both under one management, are at Ruby, Madison county, Montana, about 80 miles southeast of Butte. The principal work is in Alder gulch, the mouth of which has an elevation of 5200 ft. above the sea. The locality is only 50 to 60 miles from the Yellowstone National Park and is reached by rail by the Northern Pacific branch line from Whitehall to Alder. When N. S. Shaler and his associates acquired the Conrey

CONREY NO. 2 IN WINTER, BEFORE THE 14-FT. OPEN-CONNECTED CHAIN WAS CHANGED TO 9-FT. CLOSE-CONNECTED.

and Poor Farm properties, between 1896 and 1898, the art of dredging was in its infancy in this country, and the value of the gravel in these tracts of land was lower than that of any which had previously been worked successfully by any other process than hydraulicking. As physical conditions prohibited the hydraulic system, it was a bold project

UNDER-CURRENT AND SLUICES ON NO. 3.

that Shaler initiated, since it required the designing and operating of machinery not hitherto used.

The first attempt at working the ground was in connection with that part of Alder gulch known as the German bar. Here a central tower was constructed, to which were attached cables, washing appliances, and sluice-boxes, and the gravel lifted and conveyed to the elevated washing appliances by scoop buckets operated by wire-rope traction. This system failed to show a profit and was abandoned in 1900.

*Prepared to accompany the general review of gold-dredging in 1911 by Mr. Janin.

The next effort was made at the mouth of the gulch, where the gravel was excavated and handled by a device known as the Heyward machine. This was discontinued in 1898. The first dredging was attempted with a boat that was built in 1897 in the Grasshopper district, Montana, and was known as the Maggie Gibson. It was one of the earliest bucket-elevator dredges in this country.

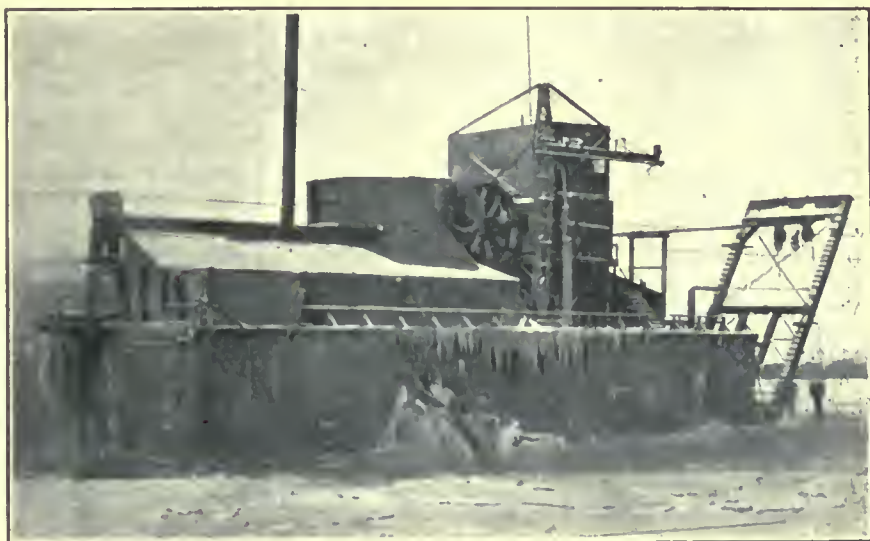

The Conrey company started with the best type of dredge known at the date of its erection. It was an elevator steam dredge with open-connected continuous bucket-line and the sluice system of gold-saving devices. The boats were progressively increased and the size of buckets used at the time of erection was in advance of the current practice of that period.

Altogether, the two companies have had 7 dredges at work on their ground; 3 steam sluice-dredges; 1 electrical sluice-dredge; 3 stacker table-dredges of the type used in California. The three steam dredges have been dismantled and discarded, and the companies now have a fleet of four boats at work. No. 3, an electrical sluice-dredge, is still in commission and doing good work. This dredge is the largest and most perfect type of this class of dredge in the world. It was designed in 1904 and started work in 1906. A detailed description of the steam dredge and of No. 3 has been given by J. P. Hutchins.* Three California type dredges have been constructed since the death of Shaler (1906), and under my advice as consulting engineer. They have been built on contract by the Marion Steam Shovel Co. after competitive bidding.

No. 1 is specially constructed for working up Alder gulch on material which has been previously worked by placer miners who left an irregular accumulation of debris. This dredge has a short string bucket-line of 7½-cu. ft. close-connected buckets, and an exceptionally long stacker in proportion to the length of the ladder. It has worked up the gulch for several miles and, under favorable conditions, has excavated a monthly yardage of 140,000, with an average of about 90,000 yd.; depending on the gravel and season. No. 2 has a 9-ft. close-connected bucket chain, with a capacity to dig to a depth of 35 ft., and has dug from 75,000 cu. yd. to as high as 140,000 cu. yd. per month. No. 3, as first constructed, has been described by Mr. Hutchins in the article mentioned; but of late has been modified considerably. It has been given greater flotation and a close-connected 9-ft. bucket chain substituted for the first open-connected bucket line. No. 4 started work in June of this year.† It has a rated capacity per month of 300,000 cu. yd., but this depends on the nature of the gravel. The highest yardage up to the present is 260,000. This dredge is, I believe, as large as any other dredge now at work in the world. The hull is 150 by 58 ft. wide by 13 ft. deep; the bow, stern, and well are all sheathed with light steel plates for winter work in ice, which also requires an exceptional depth of hull. The ladder is 160 ft. from centre to centre of tumblers, with eighty 16-cu. ft. buckets weighing 4468 lb. each; stacker, 130 ft. long; steel spuds, 44 tons each; washing screen, 50 ft. long by 9 ft. 9 in. diameter, perforated plates ½ in. thick, lower end with ¾-in. holes. The gold-saving tables have an area of 2956 sq. ft. The tables were designed in accordance with my suggestions following our experience with gold-saving devices. The sluices coming from the upper sections on each side of the 9-ft. washing screen are made

longer for the upper sections and gradually reduced toward the end, and the system of under-currents found effective on No. 3 pontoon is also employed at the lower end of the table sluices, but in a modified form. The photograph shows the bending of the sluices and also the device designed by Mr. Pryer for the clean-up tables.

In many respects, conditions of dredging at Ruby, Montana, are similar to those existing in California. The bed-rock is a volcanic ash similar to that at Oroville, but possibly of a more clayey and tenacious nature. The gravel is compact and tenacious, but not cemented or hard as the hardest in Oroville district. It, however, has occasional boulders larger than those found in California. The chief disadvantage of the Montana workings over those of California is the severity of the winter climate, where the thermometer is known to fall as low as 30 to 40°F. below zero. The two companies have, for the most part, kept their dredges at work through the year, but it is doubtful whether it would be wise to continue working through the year, were it not for keeping together an excellent, trust-

CONREY NO. 3 SLUICE-BOX DREDGE AT WORK IN WINTER.

worthy, and efficient lot of men that have been together under the able management of Charles Kammerer.

The average wages of Montana are also in advance of those in California, and the working costs at Ruby have been somewhat in excess of those in California. During the winter season dredges have twice sunk and been badly damaged, and costs have thus been made exceptionally high. The system of keeping accounts also takes into consideration bucket-ladder renewals. In spite of all these factors, the average cost for the past two years has not been much over 7c., and some months has run below 6c. per yard. It is hoped to still further reduce these figures when No. 4 has had, with the other dredges, a completed full year's run.

The Conrey and Poor Farm companies, between them, have 2500 acres of ground, all of which, however, is by no means dredgable. In addition to the fleet of dredges, the companies have a very extensive machine-shop equipment, and they do all their repairs at their own shops, and, in fact, the assembling and machining of much of their bucket-lines. They also have a complete transformer station for reducing the line tension from 80,000 to 2200 volts. The companies issue no printed annual report, as there are but few shareholders, and these in no way speculate in the stock. The main shareholder, though indirectly, is Harvard University, which inherited the interests of Gordon Mackay and of N. S. Shaler, who at the time of his death was the largest stockholder. I am not in a position to tell accurately the amount of gold return for 1911, but it will probably run from \$550,000 to \$600,000.

THE Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 172 of \$65,100 on January 4, 1912. This makes the total amount of dividends paid \$13,225,059.

*Eng. & Min. Jour., June and July, 1907.

†For details see Floyd Bushnell, 'Dredging at Ruby, Montana,' *Mining and Scientific Press*, Nov. 25, 1911.

Utah

By W. A. SCOTT

According to compilations made at Salt Lake City the ore production of Utah in 1911 was approximately 6,680,000 tons, of which Bingham district supplied 5,871,000 tons; Park City, 124,000, and Tintie 404,000 tons; 25,000 tons was shipped from Beaver county, 20,000 tons from other districts, while about 239,000 tons was mined and milled at Mercur.

Dividends.—The following is a list of the dividends paid during the year, the aggregate being \$8,973,856, a substantial increase over the amount for 1910:

Bingham-New Haven	\$ 261,558
Boston Sunshine	5,632
Cliff	30,000
Colorado	180,000
Daly-Judge	45,000
Daly West	162,000
Gemini	30,000
Grand Central	25,000
Iron Blossom	320,000
Moscow	15,952
Opohongo	10,000
Sioux	89,400
Uintah Treasure Hill	106,292
Utah Copper Co.	4,703,022
Uncle Sam	75,000
Utah Consolidated	150,000
United States S. R. & M. Co.	2,770,500
West Mountain Placer	5,500

Smelter Products.—The four smelting plants which were operated during 1911 were the two belonging to the A. S. & R. Co., at Murray and Garfield, the lead smelter of the United States company at Midvale, and that of the International at Tooele. These plants were not operated exclusively on Utah ores, a considerable tonnage having been received from Idaho, Nevada, and Colorado. The following figures show the quantity and value of the metals produced at the four smelters for the year:

Gold—240,039 oz. @ \$20.67	\$ 4,961,606.13
Silver—12,573,931 oz. @ 53.27c.	6,698,233.04
Lead—117,593,855 lb. @ \$142.	5,197,648.39
Copper—131,782,916 lb. @ 12.27c.	16,169,763.79
Zinc—10,541,198 lb. @ \$5.71	601,902.41
Total value	\$33,629,153.76

The United States Smelting, Refining & Mining Co. has operated the lead furnaces of its Midvale plant during the year, having treated about 800 tons of ore per day; but no effort was made to operate its copper furnaces, although its success in controlling smelter fume has resulted in all injunctions having been dissolved by the courts. Before starting the copper furnaces, a bag-house probably will be erected. The International Smelting & Refining Co. operated two or three of its reverberatory-furnaces during the year. During the last two months of the year an average of 800 tons per day of copper ore has been smelted. In the meantime two blast-furnaces for lead smelting have been constructed. It is understood that these will be blown in soon after the first of the year. A bag-house for handling the lead fumes from the furnaces has been built.

Bingham District.—The Utah Copper Co., for the first quarter of 1911, produced 21,296,709 lb. of copper; 24,469,812 lb. for the second quarter, and 25,851,456 lb. for the third quarter, making a total of 71,617,977 lb. for the nine months ended September 30. This was an average monthly production of 7,957,553 lb. The average cost of producing copper for July, August, and September, after making allowance for smelter deductions, was 7.56c. per lb., as compared with the cost of 8.02c. for the preceding quarter. The cost of production for September was 7.18c. The company's two concentrating plants at Garfield treated

1,273,373 tons of ore during July, August, and September, the average grade of which was 1.4829% copper. The larger of the two concentrating plants, known as the Magna, has the capacity of 12,000 tons per day, and it has been operating at full capacity since August 1. The smaller mill, called the Arthur, was planned for 13 sections, and to have a total capacity of 8000 tons per day; five sections were built and have been in operation since September 1, treating 3000 tons per day, and the sixth section has since been completed and put in operation. When the Arthur plant shall have been completed as to the 13 sections contemplated, the company will have facilities for concentrating 20,000 tons of ore every 24 hours. The extraction during the year was close to 70%. Of the tonnage of ore treated during the quarter ended September 30, about 24% resulted from underground mining, and 76% was the output of steam-shovel operations. While official figures for the last quarter of the year are not available, it is learned from a reliable source that this company's copper production for October was 8,666,729 lb., and for November, 9,117,961 lb., making a total for 11 months of 89,402,667 lb., and that the product of December operations, not yet given out, will bring the year's output up to approximately 98,000,000 lb. of copper.

The Utah Consolidated company is mining daily 600 tons of ore from its Highland Boy mine, and this is transported to the International smelter by aerial tramway. A large amount of development has been accomplished within the year, including the sinking of a 3-compartment shaft from adit No. 7 to a depth of 400 ft. This shaft was equipped with an electric hoist. The Ohio Copper Co. has operated its mine and mill steadily during the year. Close to 2000 tons per day of ore averaging 1.3% copper has been concentrated. The capacity and efficiency of the mill has been enhanced, it is claimed, by the use of Wall rolls and slimers. Fifteen rolls of this pattern have been put in, and others are to be added to the present equipment. It is reported that milling costs have been reduced to 31c. per ton, mining costs are said to be 25c. per ton, and haulage, through the Mascot tunnel, to cost 15c., making a total of 71c. per ton. The saving is about 63%. The Bingham Mines Co. has been shipping about 3000 tons per month of copper ore and 60 tons per day of lead ore, and has performed a large amount of development. Much exploration and development has been done during the year on the three known veins of the Dalton & Lark group. The Bingham & Garfield railroad, 20 miles in length, was completed September 16, 1911. This line was built by a company controlled by the Utah Copper Co.; it extends from the latter company's workings at Bingham to the mills and smelter at Garfield, and was built at a cost of \$3,000,000.

Tintie District.—The year's operations in Tintie district resulted in the extraction and shipment of over 8000 railroad cars of ore to the smelters, which was about 700 cars in excess of 1910 shipments. The Centennial-Eureka was the largest of the producers, its output having been over 2000 earloads; the Iron Blossom has second place with nearly 1700 cars. Following these two, the main shippers were as follows, the figures in each case being for 11 months ended November 30: Dragon, iron ore, 692 cars; Grand Central, 502; Colorado, 387; Gold Chain, 249; Uncle Sam, 212; Chief Con., 165; Gemini, 169; Sioux, 167; Bullion Beck, 144; Black Jack, 156; Seranton, 153; May Day, 151; Mammoth, 121; Yankee, 114; Opohongo, 92; Eagle & Blue Bell, 83; Beck Tunnel, 56; Victoria, 53; Ridge & Valley, 32; Lower Mammoth, 31; Eureka Hill, 22; Iron King, 18; Swansea, 10 cars. There were other smaller producers, shipments from which aggregated about 60 cars. The list of dividend-paying mines given herewith contains the names of eight Tintie properties, including the United States company, which owns the Centennial-Eureka and Bullion Beck in this district. The Opohongo and Gold Chain, near Mammoth, and the Victoria and Chief Con. at Eureka, are the newer properties of the district, on which development has resulted in exposing bodies of shipping ore. Within the year some new bodies of ore have also been found in the Mammoth; and important discoveries were made on the

2200-ft. level of the Grand Central. Good progress was made in developing the Victoria, Eagle & Blue Bell, and Chief Con. The upper workings of the Gemini are being operated by lessees, this work being in oxidized ore; the shaft has been sunk to a depth of 1960 ft., 200 ft. of which is in sulphide ore, which is not being shipped. The usual progress has been made in the Uncle Sam and May Day. The Yankee company has been shipping ore contained in a dump of 19,000 tons. The ores in the north end of the district, including those produced by the Uncle Sam, Yankee, Colorado, and Iron Blossom, consist mainly of silver and lead; while those of the Centennial-Eureka, and contiguous properties, contain gold, copper, and silver.

Park City District.—Ore shipments from the mines of Park City district for 1911 aggregate close to 124,000 tons. The following are the names of the principal producers, with the tonnage of each for 11 months ended November 30: Beggs concentrator, 171; Daly-Judge, 28,347; Daly West, 38,000; Grasselli Chemical Co., 6572; Hanson Bros., 261; Little Bell Con., 3499; New York Bonanza, 331; Ontario lessees, 4913; Silver King Coalition, 29,812; Silver King Con., 177; Virginia lease, 284 tons. Those found in the dividend list are the Daly-Judge and Daly West. The Silver King Coalition, usually standing at the head among dividend payers, was prevented from paying dividends the past year by the litigation in which it was involved with the Silver King Consolidated. The outcome of this was a judgment against the Silver King Coalition Co. in favor of the Consolidated for about \$725,000. The case is to be finally decided this year by the United States Court of Appeals. During the year the Silver King Coalition performed important development, and completed the work providing for electric power for all purposes at the mine, shops, and mill. The Silver King Con. opened a new body of ore on the 1550-ft. level of its Andes claim. This ore-body has been followed 600 ft., and is about 12 ft. wide.

The Daly-Judge company has reduced its mining and milling costs, and within the year a connection has been made between Daly-Judge workings and the 1550-ft. level of the Daly West, whereby the Daly-Judge is drained to the 1900-ft. level. Within the next three months a similar extension of the 2500-ft. level of the Daly West is to be made into Daly-Judge ground. The Snake Creek drainage adit, largely controlled by Daly-Judge stockholders, which is being driven into this territory from the opposite side of the Wasatch range, has been advanced over 4000 ft., one section of swelling ground in which is supported by reinforced concrete. The Daly West, besides keeping up shipments of ore and operating its mill, has carried on about 2000 ft. of development per month. It produced 8100 tons of crude ore and 23,000 tons of concentrate. The Daly West, Daly-Judge, and Silver King Coalition companies have united in a plan of impounding the tailing discharged from their three mills, and for this purpose a tract of 700 acres has been purchased. The Ontario was a heavy producer under the Crowther lease, the ore mined consisting mostly of fillings in old stopes, which were found profitable. The year's development on the American Flag mine has been mostly in bodies of sulphide ore from the 800 down to the 1100-ft. level. The assays of samples taken show this ore to contain 15 to 30 oz. silver, \$3 to \$4 gold per ton, and 5 to 10% lead. The higher levels yielded oxidized ore carrying silver and gold in the ratio of \$2 in silver to \$1 in gold.

Considerable development has been done and much interest aroused in operations in the mineralized country between Big Cottonwood and Little Cottonwood canyons, with Alta as the centre for the latter. Among the properties are the City Rocks, including adjoining properties acquired, the Flagstaff, Emma, Vallejo & North Star, Grizzly, South Star, Columbus, Prince of Wales, and Albion. The probability is that eventually these properties will find an outlet for their ores through transportation adits into Big Cottonwood canyon, where there is an excellent road to the valley.

Minor Districts.—Beaver county mines have been more productive than in 1910, as have those of Ophir and Stockton.

New Mexico

By far the most important event connected with the mining industry of New Mexico in 1911, was the completion of the Chino mill and the entrance of the Chino Copper Co. into the ranks of producers. While not the largest of the new producers of 'porphyry copper,' the Chino is in some particulars the most interesting. The company owns the Santa Rita, the oldest copper mine in New Mexico if not in the United States, a property which has produced at intervals since 1804. Yet when the new mill began work in the fall, the ore reserve was estimated at 45,000,000 tons of 2.35% copper, of which 70% can be won by steam-shovel mining. This result of the application of new methods to an old property speaks well for the manager, John M. Sully, and his able associates. The mill is at Hurley, 9 miles from the mine, and the concentrate is shipped to El Paso, where the A. S. & R. Co. smelter has been reconstructed to handle the output.

In the Pinos Altos district, Corrigan, McKinney & Hutchinson made a valiant effort to resurrect the Western Belle without tangible results. Zinc shipments from the district to Colorado, however, began within the year, and development was quietly carried on in a number of properties. In the Burro mountains the Savanna Copper Co. continued drilling, and in Socorro county the Tri-Bullion, Deadwood, Treasure, Gold Dust, Maud, Socorro, Ernestine, and other companies did good work. The American Z. & L. Co. took a bond on the Lynchburg, the Treasure introduced Oliver filters, and the Mistletoe M. Co. built and started a dry-concentrating plant. In technical lines the most interesting event was the success scored by the De La Vergne oil-engines at the Deadwood mine. Despite the long haul of fuel, the cost was reduced to 11c. per horsepower-day. This is so much below the cost of steam-power with wood for fuel that similar engines have been ordered by the Ernestine and Socorro companies. One significant event of the year, not to be overlooked, was the distribution of the excellent monograph on the 'Ore Deposits of New Mexico,' written by Waldemar Lindgren, L. C. Graton, and C. H. Gordon of the U. S. Geological Survey. It is much the best general treatise of the sort available.

Washington

Mining operations in the State of Washington for 1911, as compared with those of 1910, resulted in an increase of about 10% in gold, 14% in silver, and a small decrease in the production of lead, which was slightly above 1,000,000 lb. The copper production for 1911 was approximately 261,000 lb., as compared with 86,000 lb. in 1910. The gold production came principally from Republic, though there was considerable produced at Orient and the Okanogan country, and also in the Cascade range. The silver output came from Stevens and Okanogan counties, and the Cascades. Lead ore was mined at Metaline, Cut Bank, and Bossburg. The Napoleon mine, situated between Orient and Marcus, produces iron ore with which there is considerable gold. The oxidized ore is milled and the gold recovered by amalgamation. The iron ore is shipped to the British Columbia Copper Co.'s smelter at Greenwood.

The bulk of the copper ore mined in eastern Washington was supplied by the United Copper Co., operating at Chewelah. In the western part of the State there has been some copper production in the Cascade mountains, also in the Olympic range.

The Republic Mines Corporation, Knob Hill, San Poil, North San Poil, Quilp, and others have been active the past year, near Republic, and there has been a good deal of ore shipped, though the low-grade ore is being held till the mill of the North Washington Power & Reduction Co. is ready to treat ore, which will be January 1912. The tungsten mines, 30 miles north of Spokane, have been developed to some extent during the year, and some of the ore has been concentrated. The First Thought mine, a gold property at Orient, has been idle for some time.

Idaho

By W. A. SCOTT

The Coeur d'Alene.—The 1911 operations in the Coeur d'Alene mining districts were characterized by a general increase in ore extraction from the mines and some advances in metallurgical work. There has been, as compared with 1910, a considerable increase in the shipment of first-grade ore and a still greater increase of the tonnage of concentrate. Within the year, the Bunker Hill & Sullivan, the Hercules, the Stewart, the Gold Hunter, and the Monarch have each increased their milling facilities. In the Morning mill of the Federal company improvements have been made in the coarse concentration department, and an auxiliary plant has been built and put in operation for treating, by tube concentrators, the middling and tailing, containing zinc sulphide and iron oxide. The plant of 119 tubes probably will be doubled in capacity; this method of recovering zincblende formerly lost in the tailing is attracting much interest, and is considered successful. The Bunker Hill & Sullivan company, besides operating its two principal concentrating mills on

level. Gold Hunter as a name is not now applicable to the property, which is a lead mine. The Snowstorm mine, three miles east of Mullan, the only copper mine in the Coeur d'Alene, has kept up shipments of silicious ore to various smelting plants to be used as converter lining. To describe what was found by driving the lowest adit to the Snowstorm orebody would require a special article. The higher workings yielded copper carbonate, to treat which a leaching plant was built a few years ago, but that was later abandoned. It is understood that sulphide ore has been opened on the lowest level. The Caledonia, situated near Kellogg, and facing Deadwood gulch, is one of the newer mines. It has a well defined vein, dipping about 50°, within which is both oxidized and sulphide ores, containing lead, silver, and copper, some of it being unusually high grade. Shipments have been kept up steadily during the year, and the lower cross-cut from Deadwood gulch, by which about 800 ft. greater depth below the old workings is obtained, is nearly finished. The Stewart, lying west from the Hercules, has become a heavy producer. It is an old mine resuscitated.

The North Fork country, or Murray district, has at least five producing lead-silver mines. The Coeur d'Alene North, or Monarch, has now a larger mill than in 1910, and has produced 70 to 80 cars of concentrate during the year. The most interesting accomplishment in the mine recently has been the sinking in ore below the 1400-ft. mill level. The Paragon, Black Horse, Bear Top, and Jack Waite comprise the other mines of this region which have produced some ore and are being further developed. The Bear Top and Black Horse each has a mill. The Jack Waite has an exposed vein of high-grade galena, and a lower level is being driven to open it at greater depth.

Several properties, formerly worked, situated in Sunset Peak district, have been acquired by outside investors who are beginning to reopen and equip them. Some orebodies have been developed and made productive in the Pine Creek district, lying south of Wardner. Much has been accomplished there during the year in the way of initial operating.

Salmon River Country.—The Pittsburg-Idaho mine, situated at Gilmore, Lemhi county, has been operated during the year with a force of 75 men, and has produced approximately 20,000 tons of silver-lead ore of a grade that was high enough to stand the expense of shipping to Salt

Lake smelters without concentrating. The veins are in limestone, and the ore has been opened to a depth of 400 ft. vertically. The Latest Out mine, in the same locality, is similarly developed, and has ore of about the same character and grade as that of the Pittsburg-Idaho. Its shipments for 1911 amounted to about 10,000 tons of ore. The Allie mine, which has been developed, yields an iron ore carrying gold, some shipments of which were made during the year. The Junction mine, near Leadore, has produced 20 carloads of ore that sampled over 40% lead and close to 40 oz. silver. Much of the ore is carbonate. This district and other parts of Lemhi county have become more active since the Pittsburg & Gilmore railroad was built into the Salmon river region from Armstead. The Willert mines, situated 50 miles south of Gilmore, in Blaine county, have been developed by several adits, which, with drifts, raises, and cross-cuts, have resulted in exposing over 20,000 tons of ore running about 23% lead. A concentrating mill is being erected to treat this ore. The property is in the Dome district, 25 miles northeast of Arco. A gold-dredge was built on Kirtley creek last summer and put in operation September 1. The locality is near Salmon City.

Boise Basin.—The Boston-Idaho company, which has operated a dredge of 2000 yd. daily capacity during the past three seasons at Idaho City, constructed a second dredge and put it in operation last season. The new dredge has 13¼-in. ft. buckets, close-connected, and has a rated

SUCCESS MINE, NEAR WALLACE, IDAHO.

ore direct from the mine, is re-treating tailing that accumulated several years ago, in a plant built for that purpose. This company is now mining ore from levels and stopes below the great haulage adit. The Hecla M. Co., operating the well known Hecla mine at Burke, has had a successful year, as measured by tonnage of ore mined and concentrated and by dividends paid. The mine contains ample ore reserves, and the mine and mill equipment is adequate. The Hercules company, which lost its first mill by fire in 1910, built a new mill at Wallace last winter and began operating it in April. This plant was described in the *Mining and Scientific Press* last May. Hercules ore is noted for being of good grade, a considerable tonnage is accordingly shipped without concentrating. A feature of the mining operations is the driving of a two-mile cross-cut adit from near the bed of Canyon creek at Burke to tap the Hercules orebody several hundred feet deeper than the lowest workings. This driving is in progress and will not be finished until next year.

The Success mine and mill, situated on Nine Mile creek, north of Wallace, produce a zinc-lead concentrate. Production has been kept up during the year, and the company paid dividends aggregating \$75,000. The Gold Hunter company, operating at Mullan, has increased the capacity of its mill whereby about 200 tons of ore per day is being concentrated. Great depth in the mine has been attained by driving the lowest cross-cut from the mill level, and sinking a 200-ft. winze on one of the veins below that

capacity of over 8000 yd. per day. Both dredges are electrically operated.

The following estimate of the amount of metal produced from Idaho mines in 1911 is made by Robert N. Bell, State Mine Inspector: Gold, 60,000 oz.; lead, 270,000,000 lb.; silver, 8,400,000 oz.; zinc, 8,760,000 lb.; copper, 3,300,000 lb.; estimated total value, \$18,420,000.

Mining in Alaska in 1911

By A. H. BROOKS

*The value of the total mineral output of Alaska in 1911 is estimated at \$20,370,000, compared with \$16,883,678 in 1910. The gold output in 1911 is estimated to have a value of \$17,150,000; that of 1910 was \$16,126,749. It is estimated that the Alaska mines produced 22,900,000 lb. of copper in 1911, valued at about \$2,830,000; in 1910 their output was 4,241,689 lb., valued at \$538,695. The silver production in 1911 is estimated to have a value of \$220,000, compared with \$85,236 for 1910. The value of all other mineral products in 1911, including tin, marble, gypsum, and coal, was about \$170,000, an increase over that of 1910. By using the above estimate for the output of 1911, the total value of Alaska's mineral production since 1880, when mining first began, is found to be, in round numbers, \$206,600,000, of which \$195,950,000 is represented by the value of the gold output. The total production of copper in Alaska since 1901, when the systematic mining of this metal began, is about 56,700,000 lb., valued at about \$8,170,000.

The favorable showing made by the Alaska mining industry during the year is due, first, to the very large output of copper and, second, to the greater production, compared with 1910, of the gold placer mines in the Innoko-Iditarod region. Aside from the increased production, the most important event of the year was the opening of the Copper River region by the completion of the railway into it. The industries already stimulated by this line strikingly illustrate the importance of railway communication to Alaska. As no progress was made in the opening of the coalfields, the needs for cheap fuel in Alaska are being met by the substitution of oil-burning for coal-burning engines. The importation of California crude oil is rapidly increasing, with a corresponding decrease in the use of coal. Some new drilling was carried on in the Katalla oilfield during 1911, one or two old wells being reopened and a small production made. The oil was refined and the gasoline sold in the local market.

Although most of the gold still comes from the placers, much progress was made during 1911 in paving the way for an increased output from auriferous lodes. The work was carried on in most of the gold-bearing areas of Alaska, but the most notable advances were in the Juneau, Valdez, Kenai Peninsula, Willow Creek, and Fairbanks districts. Aside from the increase in copper mining, the advances made in developing gold lode mines is the most encouraging feature of the year's operations. Dredging also made great progress, notably in the Nome region. It is estimated that, in the entire territory, 22 dredges were operated for the whole or part of the open season of 1911. In addition to those operated, at least half a dozen were in process of construction.

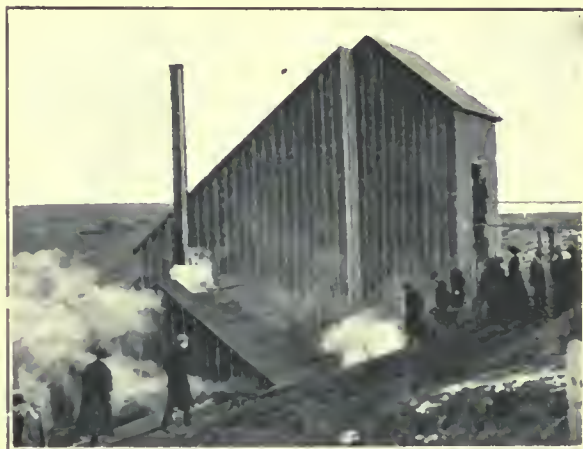

As improvement in transportation is the most important element in the advancement of the mining industry, the progress for the year in this respect will be briefly summarized. The Copper River & Northwestern railway was completed to Kennicott in April 1911. There was no other

*The annual report on the mineral resources and production of Alaska for 1911 is now in preparation under the direction of Alfred H. Brooks, of the United States Geological Survey. The more important features of this report relating to the mining development during the year are abstracted as above. Complete and accurate statistics of the mineral production of Alaska cannot be collected within less than four or five months after the close of the year, but meanwhile it seems desirable to give prompt publication to preliminary estimates, which, although not based on accurate statistics, are believed to be not over 10% in error.

railway construction in Alaska during the year, though some railway surveys were made. At the close of 1911 there are 465 miles of railway in the Territory, compared with 371 miles in 1910. This mileage is distributed among nine different railways from 5 to 196 miles in length.

It is estimated that there were 15 gold lode mines in Alaska which made some production in 1911. Custom mills at Valdez, Chena, Fairbanks, Nome, and Skagway were operated and milled ore from many prospects which cannot yet be classed as productive mines. Some development work was done during 1911 on several hundred prospects widely distributed over the Territory. The output from auriferous lodes in 1911 is believed to have been somewhat larger than that of 1910, which was valued at \$4,105,459.

Auriferous lode mining was first attempted in the Ketchi-

OPENING DAY AT CUSTOM QUARTZ MILL, NOME, ALASKA,
OCTOBER 7, 1911.

kan district some twelve years ago. Several conspicuous failures made at that time so discouraged operators that relatively little attention has since been paid to gold mining in this district. However, some development work has been continued, and in 1911 work was pushed on several properties near Dolomi and on Georges inlet. The advances made in the Portland Canal region of British Columbia stimulated prospecting on the Alaska side of the boundary and within the Ketchikan district. Some encouraging results are reported in this field.

Philippine Coal Trade

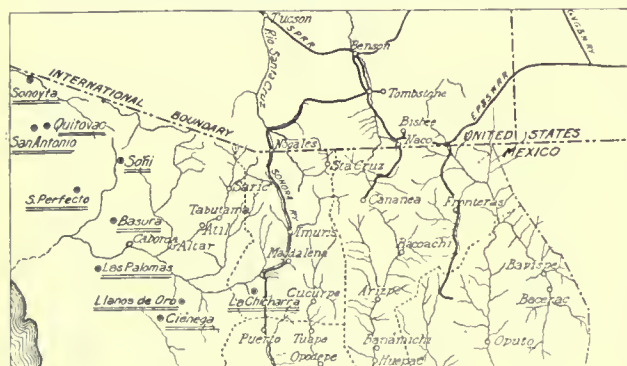

According to George E. Anderson, United States Consul General at Hongkong, the mine at East Batan in the Philippine Islands, is now turning out 100 tons of coal per day and is expected soon to be able to turn out and handle economically 300 tons. This mining enterprise, which was undertaken several years ago, at first proved a financial failure, and some time ago it was placed in charge of William E. Nolting under an agreement between the company and its creditors. This receiver or manager, in connection with E. R. Hix, a coal expert from the United States, has reorganized the business, and it is now said to be upon a paying basis. The Government of the Philippines has aided the enterprise by advancing funds against contracts for coal. These contracts are now gradually being carried out. The imports of coal into the Islands in the year ended June 30, 1911, amounted to 403,146 metric tons, valued at \$1,267,312, as compared with imports of 303,117 ordinary tons, valued at \$972,341, in 1910, 171,088 tons, valued at \$461,465, in 1909, and 213,959 tons, valued at \$567,220, in 1908. Up to 1909 Australia supplied most of these imports, furnishing 169,151 tons out of the total of 171,088 tons imported that fiscal year. In 1910, however, Japan commenced to enter the trade in earnest, apparently largely because of labor troubles in Australia. For the past two years it has furnished about half of the total imports into the Islands, through British North Borneo has commenced to enter the trade.

Mexico

By OUR SPECIAL CORRESPONDENT

In the first half of the last fiscal year Mexico's exports of gold showed a big increase, totalling ₧29,510,679, as against ₧23,178,336 in the corresponding period of the preceding fiscal year. Silver exports amounted to ₧38,805,842, as against ₧37,754,931. Gold exports for 1911 were over ₧50,000,000, and silver exports about ₧75,000,000. The production of copper was well maintained in 1911. In eleven months Greene-Cananea produced approximately 42,000,000 lb., exclusive of that from the Miami concentrate. In the same period the production of the Moctezuma Copper Co. (Phelps-Dodge) was 22,648,094 lb., an increase over the production in the corresponding period of 1910. In the ten months ended October 31 the Boleo Copper Co. (French Rothschilds) had a production of 22,167,221 lb. The Mazapil Copper Co., in the State of Zacatecas, and the Teziutlan Copper Co., in the State of Puebla, contributed materially to the year's output. Mexico's lead is principally the product of the important silver-lead mines of the northern part of the Republic, and disturbed conditions and lack of transportation facilities curtailed the output during the first half of 1911. Zinc production was also affected.

The year saw the completion of the extensive campaign of betterment inaugurated by the present management of the Greene-Cananea in Sonora, and involving an expenditure of fully ₧7,500,000. For several months Greene-Cananea has been producing copper at an average cost of 9c., and at the present rate of production and the present price of copper the company is in position to earn approxi-

NORTHERN SONORA.

mately \$1,675,000 per year. There is talk of dividends in 1912. Since the first of the year monthly gold content in the Greene-Cananea ores has increased from 468 to 763 oz., and the silver from 90,135 to 127,568 oz. During the greater part of the year Greene-Cananea has been smelting concentrate from the Miami Copper Co., under a contract made in 1910. The Calumet & Sonora Co. has put in a Huff electrostatic plant at its Cananea properties, and is getting good returns from regular shipments of concentrate. The Moctezuma Copper Co. has provided against water shortage by the construction of a dam for the impounding of storm-water. For several months the Lucky Tiger Gold Mining Co. has been operating its new 250-ton cyanide plant, and during the year it has been shipping high-grade ore. During the year small smelters have been blown in at the Mina Mexico, in the Sahuaripa district; at the mines of the Triunfo Consolidated Mining Co., near Arizpe; and at the Cerro Gordo properties near Cumpas; and 100-ton plants have been completed by the Sonora Copper Co. and the Cobriza Mining Co., both operating near Noria. Disturbed conditions have interfered with the plans of the Pacific S. & M. Co., owning, through subsidiary concerns, the Fundición and Guaymas smelters, and neither plant has been blown in. The Pedrazzini Gold & Silver Co. completed a cyanide plant this year, but recently suspended operations, pending the adjustment of labor and other difficulties. The Transvaal Copper Co., owning extensively developed copper properties near Cumpas, is

credited with plans for a concentrator, and for a railroad to Cumpas; also with negotiations for the transfer of its properties to the Phelps-Dodge interests. In ten months of this year the net earnings of the Mines Company of America, controlling the Dolores and El Rayo mines in Chihuahua and the Creston Colorado and La Dura in Sonora, amounted to \$673,109. The company has plans for reducing operating costs at Dolores by building a power plant at Madera and transmitting power to the mines. Early in 1911 the properties of the Hidalgo Mining Co., in the Parral district of Chihuahua, were taken over by the Alvarado M. & M. Co. at a price of \$500,000. Recently the Alvarado purchased the power plant of the Parral Power & Reduction Co. Milling at the new plants of the Alvarado and the Veta Colorado M. & S. Co., in the Parral district, was not interrupted by the revolution, and the bullion output has been steady during the year. The Chihuahua smelter of the A. S. & R. Co., and the Terrazas smelter of the Rio Tinto Copper Co., shut down several months ago as a result of labor troubles following the revolution, have been recently blown in. Negotiations that may result in the transfer of the Santa Eulalia mines of the Chihuahua Mining Co. and the Potosi Mining Co. to English interests are in progress. The deals involve millions of pesos. French interests are reported to be negotiating for the big lead-silver mines of the Compañía Minera de Naica. The Rio Plata and La Republica companies have been operating profitably during the year. Work is in progress on a 300-ton plant for the Palmarejo & Mexican Goldfields, Ltd. The San Toy Mining Co. has had a successful year, and has paid several dividends. The net earnings for the first half of the year were \$182,647. Development of the Buena Tierra mine at Santa Eulalia, purchased in 1910 by the Exploration Company of London and Mexico, has been attended by satisfactory results. Considerable high-grade ore has been shipped from the Dos Cabezas mine of the F. S. Pearson interests, and machinery for a stamp-mill and cyanide plant has been purchased at a cost of \$65,000.

The labor trouble at El Oro in August, which appeared serious at the start, was not prolonged, and operations were not seriously affected. During the year the Dos Estrellas company has been producing from ₧800,000 to ₧900,000 per month, with a monthly profit of close to a half million pesos. Big dividend payments have been continued. In the ten months from January 1 to October 31 the El Oro Mining & Railway Co. had a production of \$2,014,080, milling 302,860 tons of ore, and securing a profit of \$861,060. The 1911 production of the Mexico Mines of El Oro has averaged about \$127,000 per month. A report for seven months shows a total production of \$894,192 from 80,649 tons of ore, the profits reaching \$543,112. During the present year the net earnings of the Esperanza Mining Co. have been kept down by heavy charges, due to betterments of various kinds. Figures for seven months show profits of only \$247,604 from a production of \$970,029. The ore milled in that period amounted to 147,520 tons. The Real del Monte & Pachuca Co., controlled by the U. S. S. R. & M. Co., of Boston, has continued its improvement campaign during the present year, with the result that it is now handling about 32,000 tons of ore per month. The present rate of production represents an annual output of approximately 10,000,000 oz. of silver, and it is possible to further increase the tonnage handled. In June last the Santa Gertrudis company, a subsidiary of Camp Bird, Ltd., placed in commission its new 600-ton plant in the Pachuca district of Hidalgo. The company reports that the ore reserves, estimated at 462,000 tons at the time the Santa Gertrudis mines were purchased, have been increased to 1,150,000 tons, with a probable value of ₧16,500,000. In the first six months of this year the San Rafael y Anexas Co. had a gross production of ₧1,649,556, and earned profits of ₧546,114. A total of 71,587 tons was mined, the mining cost reaching ₧6.56, and the milling cost ₧3.94. The average yield was 643 grams silver and 3.43 grams gold. Dividends of ₧434,400 were paid in the six months. In the past fiscal year the La Blanca y Anexas Co., another big company of the Pachuca district, produced 67,354 tons

of ore averaging 800 grams silver and 4.06 grams gold. La Blanca recently entered into a deal to buy the Cinco Señores properties in the Pachuca district for \$600,000.

It is estimated that the 1911 production of the Guanajuato district will at least reach that of 1910, which was approximately \$14,000,000. The 40-stamp cyanide plant of the Providencia M. & M. Co., at the Tajo de Dolores, was completed early in the year, and has been in successful operation for several months. A 10-stamp cyanide plant started by the Tula Mining Co. in the first half of the year has been shut down pending the development of higher-grade ore. The Peregrina M. & M. Co. has had a good year, handling 6000 tons per month from the Villapando mine of the Cubo M. & M. Co. in addition to 7000 tons of its own ore. The Guanajuato Reduction & Mines Co. has averaged 20,000 tons per month, about one-third of the ore milled resulting from new development in the old Rayas and Tepeyac mines. Up to this year the company has been operating on ore from dumps and fills. The mill of the Guanajuato Con. has been operating at half capacity during the greater part of the year, but higher-grade ore has been milled. The Pinguico has been milling from 5000 to 7000 tons per month, and the Carmen-Guanajuato has been operating at a good profit. The year's production of the rich El Monte de San Nicolas mine will be over \$1,000,000. The Nueva Luz work, at a standstill during much of the year, was recently resumed. It is expected to cut the mother lode in February or March 1912.

The old Mololoa mines in the Hostipaquillo district of Jalisco were purchased early in the year by the Makeever interests, operating the El Favor and El Tajo properties. Since the purchase, development has been extensive and much high-grade ore has been shipped. Power interruptions during the rainy season interfered with mill operations of the Amparo company, in the Etzatlan district, and the El Favor company, in the Hostotipaquillo district, both taking current from the transmission line of the Chapala Hydro-Electric Co. The Amparo has continued dividend payments of 3% on \$2,000,000. The addition of two tube-mills has recently enabled Amparo to increase the tonnage by more than 1000 tons per month. High-grade ore from El Favor stopes is being shipped to the smelter, and the development of the sulphide ores below the 600-ft. level has been commenced. The Consolidated Mining Co. has given an option on its Casados mine in the Hostotipaquillo district. During the first half of the year much high-grade ore was shipped from this property. The year's development has been extensive. The Espada Mines Co. has built an aerial tramway to deliver Espada ores to the Virginia & Mexico plant in the Hostotipaquillo district, leased early in the year, and milling will be commenced shortly. The Cinco Minas Co. (Marcus Daly interests) has been developing during only a part of the year. Plans for a 200-ton reduction plant are being drawn. The Regina Mining Co. has had an important year of development and is ready to build a concentrating plant at its copper mines in the Ameca district. Operations of the Magistral-Ameca Copper Co. were suspended during a part of the year. Sinking of the main shaft was recently resumed. The old Cerrito copper mine in the Ameca district has been taken over by the Almoloyn Mining Co. at a price of \$50,000. The \$100,000 bond on the Zapote group of mines in the Ameca district, held by E. A. Montgomery, of Los Angeles, Cal., has been extended for a year, and extensive development has been continued. The San Miguel Gold Mining Co. has imported machinery for a reduction plant at gold mines near Ejutla. Work at the Keystone properties in the Tapalpa district has been resumed by the Mexicana Mining Co., a holding concern. The Tajo Mining Co., of the San Sebastian district, has increased its mill capacity to 100 tons.

During the year engineers of the Esperanza Mining Co., of El Oro, examined the old Esenadra mine in the Taviche district of Oaxaca with a view to its purchase by Esperanza. It is now reported that the deal has been abandoned. Much ore has been shipped during the year from the San Juan mine in the Taviche district, shipments reaching a value of \$100,000 per month. The San Juan company has installed

a hoist for deep sinking, and is planning the erection of a 200-ton mill to handle the lower-grade ores. Oaxaca operations were not affected to any extent by the political upheaval. The most important transfer of the year was that of the Tiro General in the State of San Luis Potosi, the mines and 10 kilometres of railroad passing to the A. S. & R. Co. for \$1,600,000. For a number of years the Tiro General has been an important shipper to the Aguascalientes plant of the A. S. & R. Co. The railroad gives the mines connection with the National Railways at Las Charcas. The Santa Rosa Mining Co., controlled by the Exploration Company of England and Mexico, has been at work on important reduction facilities at the Santa Rosa mines in the Concepcion del Oro district of Zacatecas. Operations in the principal Zacatecas districts have been well maintained. Important shipments of lead-silver ore have been made from the Lead Queen mine in Aguascalientes to the San Luis Potosi smelter, the smelter company having the prop-

MINES OF JALISCO.

erty under lease. From the Taxco district of Guerrero ore has been shipped during the year by the Atlixiae, San Miguel, Mora y Milagro, Espiritu Santo, and San Miguel concerns. Atlixiae also has shipped concentrate and precipitate, and concentrate has been shipped from the Purisima and Chorrillo mills. There has been much development by the Taxco Mines of Mexico at the old Rosario properties, and plans for a 200-ton cyanide plant have been taken up. The Reforma M. & M. Co., owning the big Campo Morado properties, has been operating steadily.

The Mexico Con. M. & M. Co., owning extensive properties and a reduction plant in the Guanacevi district of Durango, was reorganized during the year, and since has been operating with satisfactory results. It is reported that English interests have made a deal for the Restauradora properties in the Guanacevi district, at a price of about \$1,000,000. The Candelaria Con. Co., of San Francisco, California, has built a 100-ton cyanide plant at its mines in the San Dimas district of Durango, and is abandoning the old system of pan-amalgamation. The capacity of the plant will be increased after the completion of a hydro-electric plant. The San Luis Mining Co., another San Dimas concern, is replacing an old 30-ton plant with a cyanide plant of 100 tons capacity. The Compañía Exploradora y Explotadora de Guanacevi is pushing development work, and has entered into a contract to supply 50 tons of ore per day to the Rosario M. & M. Co. The Reyes M. & S. Co. has blown in a 50-ton lead smelter, and is operating with success. A contract for a new power plant at the Guadalupe de los Reyes mines in the State of Sinaloa has been signed, and the new plant will be ready for service by May 1912. Charcoal gas-producers will be used, and a big saving in operating expenses is expected to result.

Lake Superior Copper Mines

By ROBERT H. MAURER

As nearly as can be calculated at this time, actual figures in most instances not being available, the output of the Lake Superior mines for the year 1911 approximates 222,874,350 lb. fine copper, representing a gross value of \$27,859,375. This output was made at a cost of about \$22,000,000 or an average of 10c. per lb. for all companies, and all but about 15,000,000 lb. was produced at a profit. Omitting a production largely incidental to development in the various properties, and considering only the output of the profitable producers, the average cost was about 9.5c. per lb. Twenty-two companies contributed to this output, as against 20 in the preceding year, and there are now 18 yielding a regular production with a combined annual output not far from 220,000,000 lb. fine copper. There is little likelihood that the present rate of production will materially increase in the next year or two, though a 5% increase is easily possible. New sources of production are seemingly limited to the Lake Copper Co. and will show no marked effect on the annual rate for a year at least. Any material increase must come from one or several of the present producers and may be looked for only in the event of further and great improvement in the metal market. There is no undue restriction on output except in case of the Osceola and Calumet & Hecla, both of which are capable of far greater production. The other companies for the most part are producing well up to capacity. A table showing the estimated production in pounds fine copper of the several Lake Superior companies for 1911, as also actual figures of production for the preceding year, is appended herewith. Estimates are based upon the most reliable data obtainable. Official figures will not be available in some instances for several months to come.

Company.	1911. (Estimated.)	1910. (Actual.)
Calumet & Hecla.....	75,434,000	72,672,469
Copper Range Con.:		
Champion mine	17,845,000	19,224,174
Baltic mine	16,329,000	17,549,762
Trimountain mine...	7,200,000	5,694,868
Quincy	21,398,000	22,517,014
Osceola	18,261,000	19,346,566
Abmeek	14,926,000	11,844,954
Mohawk	11,937,000	11,412,066
Wolverine	9,642,000	9,665,534
Tamarack	7,514,000	11,063,606
Isle Royale	7,292,000	7,567,399
Allouez	4,725,000	4,655,702
Superior	3,213,000	3,181,041
Centennial	1,499,000	1,572,566
Mass	1,429,000	1,321,885
Victoria	1,415,000	1,164,564
Franklin	1,000,000	966,353
Winona	800,000
Hancock	754,749
La Salle	245,000	472,100
Gratiot	15,605	265,869
Miscellaneous	262,031
Totals	222,874,354	222,420,523

The average price received for all copper sold during the year was 12.65c., which, with one exception, is the lowest annual average price recorded in ten years. The average for the decade was 15.12c., and in 1907 was 20c. Since that year it has ruled steadily under 13.5c. The end of the year brought material improvement in the metal market, and at the close the better grades of copper were selling freely at above 14 cents.

In consequence of the low price realized for the product, dividends were generally smaller and not always earned. The total disbursed by all companies during the year closely approximates \$6,000,000.

New York Share Market in 1911

By OUR REGULAR CORRESPONDENT

Falstaff said: " * * * My whole charge consists of ancients, corporals, lieutenants, gentlemen of companies, * * * slaves as ragged as Lazarus in the painted cloth, the cankers of a calm world and a long peace." In an attempt to review the mining share markets of the year in the East, there seems to be almost as little to be proud of as Sir John found in his motley band of riff-raff. The year 1911 will always be recalled as a period which broke all previous records for depression. Trading in mining shares in New York is carried on mostly on the Curb, an outside market without any organization, but whose members follow closely the rules of the New York Stock Exchange. This market, which really occupies a legitimate field among the various market-places of the Eastern financial centre, has been used by so-called brokerage houses making the bucketing of orders a regular practice, until the Curb has lost its public and can no longer fulfil its primary office—that of making a market for the distribution of new issues. The atmosphere of the New York Stock Exchange is distinctly hostile to all mining enterprises; in fact, it is one of the traditions of the Exchange to treat with unbounded contempt anything connected with the mining industry, at least so far as public trading is concerned. There are those who dare to say that this is short-sighted, and who point to the building up of business which does not go to the floor of the Exchange and in which mining plays a very large part, but so far there has been no sign of any change of attitude by the board of governors.

The beginning of 1911 found market operators turning from the copper shares, which were evidently facing a period of stagnation, due to the burden of accumulated stocks. The conditions prevailing at the beginning of the year clung to the copper market throughout nearly the whole of 1911, and only in the latter half of December was there any strong upturn. Throughout the year, the copper situation was an exceedingly interesting one—one which was followed by the general public with close attention as well as by producers, sellers, and consumers. The whole of 1911 must be counted a period of stress for the copper producers, a period devoted largely to close study of cost sheets in an anxious effort to meet conditions. The year just begun will undoubtedly demonstrate that the depression of 1911 was by no means an unmixed evil. Forced rehabilitation of many properties has been completed, development work has been accomplished, and economies enforced that will all add to profit in the future. The Canadian silver issues—all Cobalt properties—with only one or two exceptions, demonstrated one of the queer turns of public sentiment as regards mining shares. The close of 1910 showed that the mines in Cobalt had broken all previous records, dividends were satisfactory, in some cases very large in proportion to the market prices for the shares, but the public trading had then dwindled to insignificant proportions, and in spite of increased production throughout the year, market followers refused to have anything to do with Cobalt issues.

Trading in Nevada issues had sunk to very small volume during 1910, and when Goldfield Consolidated was 'taken inside', as the phrase goes, meaning its removal to the floor of the Stock Exchange, Goldfield shares were left without a leader and almost without any public following. It appeared, therefore, that there was no obstacle in the way of the development of a new mining field. Especially if a gold-mining district, with the lodestone of high-grade gold ore, could be brought before the public, then another real boom could be made in a market way, and many thousand shares distributed. So it was that Porcupine dawned, with every mining broker, promoter, and advertising solicitor watching its rise with anxious eyes. Early in the year, the prospectors, claim-owners, and option-holders moved upon New York in solid phalanx, with tongues trained to speak of no sums less than hundreds of thousands. Hun-

dreds of pounds of rusty rich quartz, heavy with free gold, came to New York in ore-sacks and grips. One or two deals were made at greatly inflated figures, and Porcupine owners began counting their millions. The share market was prepared for wild performances when a perceptible chill began to be felt. The Englishmen who came into Canada, came and went, their going accompanied by rather lame explanations, for the most part, and the fire in midsummer swept away practically all the anticipated boom. The public never took any interest in Porcupine, so far as New York is concerned.

Boston, which is the market for the Lake copper shares, was in a turmoil during the greater part of the year on account of the consolidation attempted by the Calumet & Hecla; a move which was fought so bitterly as to be finally abandoned by its promoters. The situation was made more interesting by the work of J. R. Finlay, formerly manager of the Goldfield Consolidated, who made an independent appraisal of the principal Lake properties for the Michigan State Board of Taxation and Equalization. Mr. Finlay has some advanced ideas about mines and mining investments that ought to be read by every would-be buyer of mining shares, before he makes his purchases—not after. For Boston, like New York, the year was one of low prices and a very small volume of business. One of the principal deterrent factors to normal activity in mining enterprises was the Mexican insurrection, which resulted in the exile or flight of General Diaz. New York has many mining men, promoters, and engineers, to whom, for many years, Diaz was Mexico, and it is not strange that confidence, uprooted by the downfall of Diaz, should have been slow to be recovered. New York has many interests in Mexico and is hoping for an immediate restoration of tranquillity. One of the brighter features in the mining-share market was the revival of Tonopah. The making of a big mine of the Belmont, and coming back of Montana-Tonopah, gave one group of operators a cheerful air of prosperous business.

Any study of the mining market in New York City begins and ends with an analysis of the peculiar conditions surrounding the Curb market. In reality, the Curb market is simply an outgrowth of custom. It is granted the privilege of trading in the street by a stretch of the police power, and holds its sessions in the open air during the whole year. The bulk of its business is in mining stocks, in new issues not yet granted the privilege of trading on the New York Stock Exchange, and the greater part of the business comes through members of the Stock Exchange. It is one of the iron-clad rules of the Exchange that members are not allowed to trade with the rival exchanges. It has, therefore, been impossible for the Curb to organize itself without losing the overflow business from the big exchange. In fact, its members with Stock Exchange connections have been strong enough to prevent any real organization being effected. This peculiar situation has left the Curb without power to redress any wrongs committed by the traders who abuse the privileges of the open market. The Curb has been, and is still, unable to enforce any sort of discipline or punishment upon traders transgressing these unwritten rules. Could this anomalous condition be overcome, the New York mining market would immediately achieve an enthusiastic public following that would grow to immense proportions.

If the mining engineers of the United States could, through some official organization, impose conditions which would prevent any reputable engineer from lending his name to 'get-rich-quick' paper promotions, foisted upon the public by promoters, that bear no real relation to the mining industry, it would mean a tremendous double step forward. The public realizes mining to be a field in which it should be able to embark profitably. The same public has just recently begun to realize the need of common sense and business judgment in making such embarkations. New York will never have one-half the mining market it should have until some preventive measures are adopted which will be more effective than the mere example of the punishment of those who use the United States mails for fraudulent purposes.

California Petroleum Production

The production of the various California oil districts in 1911, less the fuel used in the field, is given below:

	Bbl.
Midway	20,821,669
Coalinga	17,793,221
Kern River	12,225,273
Santa Maria	6,259,766

Market Reports

LOCAL METAL PRICES.

San Francisco January 3.

Antimony	11-11½c	Quicksilver (flask)	44.50
Electrolytic Copper	15-16½c	Tin	47-48½c
Pig Lead	4.70-5.65c	Spelter	7½-8½c
Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50			

METAL PRICES.

Silver reached the highest point for the week ended January 3 on last Wednesday, when New York quotations placed it at 54½. The week opened strong at 54½, but on Saturday the price dropped to 54½. Since then it climbed steadily to the figure named. The latest New York quotations place electrolytic copper at 13.90, lead at 4.45, and spelter at 6.30.

EDITORIAL

LOS ANGELES mining engineers have formed a committee, under the chairmanship of Mr. F. J. H. Merrill, to organize a local technical society. Whether it will be affiliated with one of the national societies has not yet been determined.

SHIPPING interests are 'after the scalp' of the Court of Commerce, and will make an effort to secure its abolition, on the ground that appeals from the decisions of the Interstate Commerce Commission should go directly to the Supreme Court.

NEW MEXICO is at last a State of the Union, and will duly celebrate the event next Monday. New Mexico has had a long and interesting career as a Territory, it is a region of large, undeveloped resources, and we are glad to wish that as a State it may realize to a full its best ambitions.

EXTENSION of the operations of the United States Smelting, Refining & Mining Company into States other than Hidalgo, forecasted by an item in our news pages, will be welcomed in Mexico, where the company, as at home, is well liked and has a record of clean dealing and achievement.

WHAT'S in a name—"The largest open-cut mine in the Federated Malay States, situated at Kamunting, Perak, belongs to Towkay Ng Bôo Bee, who has had a very tempting offer from a London syndicate. The conservative old gentleman, however, is not disposed to sell." He is evidently neither booby nor n. g., after all.

TROUBLE with the farmers over smelter fume has again come to a head in California. This time the Farmers' Protective Association is asking action against the Penn Chemical Works at Campo Seco, in Calaveras county. Such matters should be settled by a joint technical commission rather than a board of county supervisors. Unfortunately, as yet this seems impossible.

TEPIC, the ancient capital of the Territory of the same name in Mexico, will be in railroad communication with the rest of the world after February, and construction of the Southern Pacific line on to Guadalajara is to be pushed, according to Mr. Epes Randolph. The influence of better transportation facilities is already felt, the railroad having cast its shadow before, as noted in the cheerful account of mining development in the Territory printed on another page.

LEASING the coal and grazing lands is advocated by Mr. Walter Fisher in his annual report as Secretary of Interior. While by some this is considered the essence of radical doctrine, the idea is rapidly becoming familiar and popular. On the whole Mr. Fisher's recommendations are much less revolutionary than conservatives had anticipated and, being evidently based upon thorough and fair study of actual conditions, they have produced an excellent impression.

DREDGING costs are not based everywhere upon the same method of computation. Too commonly the theoretical capacity of the bucket, multiplied by the number dumped per minute, is taken as the basis of yardage. In California practically all companies compute their returns on the basis of the ground in place that has been dug, and, to determine the amount each month, careful surveys and soundings are made. The capacity of dredges in California is therefore larger and operating costs lower than those elsewhere, with few but important exceptions, when equality of conditions is considered. The figures used by Mr. Charles Janin in his review of dredging are in each case those computed according to the local standard, data for recasting them not being available.

A SURPLUS in the United States Treasury once brought Grover Cleveland into the presidency, though, sad to relate, the surplus, having accomplished so much, promptly vanished. Another surplus, in the treasury this time of the Tonopah Mining Company, is popularly reported to have brought Mr. J. E. Spurr to the vice-presidency of that company, that he may expend it for another mine 'equally good.' We are unable to say whether there is foundation for the report, but it is evident from reading the news columns that from now on every mysterious stranger seen hanging around a likely prospect will be regarded as an emissary of the potent Mr. Spurr. We hope the Tonopah Mining Company may have a long career of usefulness. Another good mine could hardly fall into better hands, but we doubt very much whether its campaign of optioning is as wide as current news items suggest. Somebody is going to be disappointed.

MOJAVE has been the centre recently of a new oil boom engineered by the Mojave Oil Company, of Los Angeles. Rigs have been erected, certificates engraved, and drilling and stock-selling are simultaneously active. The literature distributed by the company dilates enthusiastically on the "Kraemer antiline," "plainly traceable above ground for over a hundred miles," "without a fault." The supposed oil pool is linked convincingly with the field at Maricopa, the presence between of the Tehachapi mountains being gracefully ignored. It is stated that the "drill has just penetrated through an exceedingly hard capping, and entered a brown shale, impregnated with the usual oil odor." The fact is that the drill is in igneous rock underlying all sedimentaries, and that the antiline, of which so much is made, is a minor wrinkle of no great extent. There may be oil near Mojave, but the Mojave Oil Company has represented no convincing evidence thereof, and is evidently wrong in important particulars. However, there are those who maintain that at least some oil will be found—it is hard to sell stock on an odor, even when it is admittedly strong.

FOREST SERVICE officials are at some pains to dispel the impression, so widely current, that prospecting on lands in the National Forests is to be restricted. In a circular letter recently issued by the District Forester in San Francisco, it is pointed out that the Act of June 4, 1897, specifically says that prospectors shall not be prohibited from entering upon National Forest lands for the purpose of prospecting, locating, or developing the mineral resources therein. Prospecting and mining may go on within the National Forests just the same as on public lands outside. The prospector is absolutely free to travel about and explore just as much as he pleases and wherever he pleases, without asking anybody's permission. When he finds mineral he can stake out, locate, record, and work just as many claims as he thinks worth while, precisely as he would on the public domain. Any time he wants to get

patent for his claims he can do so, providing the mining laws of the United States have been complied with. No one can patent claims which are taken up merely for the timber on them, or to get possession of land for purposes foreign to mining. The mineral as well as all other resources of the National Forests are for use. Within a National Forest the prospector and miner are assured of timber when they need it, and as long as they need it for the development of their claims. Outside, the timber supply is often doubtful. This is designed to be the chief difference between prospecting inside and outside National Forests.

ECONOMIC geology is recognized as perhaps the most difficult of all subjects, connected with mining, to teach, and in the current number of *Economic Geology* Mr. C. A. Stewart reopens the discussion as to teaching methods. It may be worth while to point out that the difficulties encountered, in part at least, arise from the necessity of covering three phases of inquiry in one course. The thorough study of the principles and criteria of ore deposition, for which Mr. Stewart pleads, must necessarily be based upon an adequate knowledge of the occurrence of deposits—what might be termed economic geography—and this, in turn, must be based upon a good working knowledge of ordinary geography. The average undergraduate mining engineer is too often devoid of the last of these, and the instructor's task is correspondingly magnified. Nevertheless, the criticism is justified, that in many technical schools too much time is devoted to the study of details, and too little to the correlation of details and the acquisition of general principles. Until by psychological analysis it is possible to determine beforehand exactly what the needs of a student will be, and to direct his education to that specific end, much as candidates for examination are coached on the questions asked during previous years, no better teaching method can be devised than a thorough inculcation of principles and methods of study. The capable man will be able to acquire detailed knowledge as it is needed, and will be the better off for not having his mental storeroom full of old lumber. Too often there is a disposition to overvalue facts and undervalue principles.

Alaska's Immediate Needs

Chambers of Commerce of the Pacific Coast cities have united in urging upon Congress prompt action covering the more imperative needs of Alaska along non-controversial lines. Attention has been so concentrated upon the railway and coal-land situation that other matters of equal importance are being overlooked. Alaska needs railways and better land laws, but, because there is dispute as to how these needs are to be met, is no reason why the present disgraceful condition of the Alaskan coast as regards light-houses and other aids to navigation, should continue. This past summer one of the steamers had occasion to run out of its regular course for a short distance in the immediate vicinity of Sitka, which, it is well to remember, has been a centre of civilization since 1799, and discovered that the coast was still unsurveyed! Not only the coast, but the land is without surveys, and while a beginning has been made by authorizing the United States Geological Survey to take up the work, it remains true that settlement is practically prohibited in most of the Territory by the fact that the land is still unsurveyed. Cable tolls are high, wagon-roads are few, the salmon are being fished out without adequate provision for the future, and in many other ways Alaska is being neglected and exploited rather than rationally developed. The Alaskans deserve better things. They have natural difficulties enough with which to contend, and

the National legislative body should not allow its attention to be focused upon polemics to the exclusion of the humble but useful matters of everyday life.

Revision of the Mineral Land Laws

There have been few times when as much intelligent public interest was focused upon National problems as now, and none probably when the laws relating to the mineral lands were under such general and active discussion. The need of thorough revision has long been recognized by those familiar with Western conditions, but inertia, seconded by self-interest, has prevented any considerable accomplishment. Both still stand in the way of adequate revision, but the demand for change is more widespread and is better organized than ever before. The withdrawals of public land from entry, first by executive act, and later with Congressional approval, have forced attention to the need of change. So long as it was possible by 'hook or crook' to continue to get possession of mineral land as needed for development it was done, and there were many who justified the particular means adopted as affording the only way open for meeting an acute situation. We are not among those who believe that good would come from a wide investigation of titles acquired under former conditions. If there were irregularities, responsibility therefor is not one-sided, and a general unsettling of titles would be a National calamity for which neither necessity nor adequate justification exists. Bygones may well be let bygones; the present and future afford troubles enough.

The American Mining Congress has maintained for several years a committee on the revision of the mineral land law. This committee, under the chairmanship of Mr. E. B. Kirby, has undertaken a campaign to secure from Congress a commission or some other authorized body to hold public hearings and receive suggestions looking to a complete re-writing of the Federal statutes relating to mineral land. This plan has received wide support and there is excellent prospect of the suggestion being adopted. In the meantime an extensive discussion is going on among engineers as to just what changes should be made. The Mining and Metallurgical Society has appointed a strong committee, consisting of Messrs. H. V. Winchell, C. W. Goodale, and M. L. Requa, to study and report on the matter. The San Francisco and other sections of the Society have debated the situation, though as yet no reports have been published. The chairman of the committee, Mr. Winchell, will be glad to receive suggestions from those interested, whether members of the Society or not.

The admirable analysis of fundamental conditions by Mr. George Otis Smith, printed in this issue, affords at once a sound basis for discussion and a well formulated statement of the position taken by the proponents of change. The country is fortunate in having just at this time as Director of the Geological Survey, one who takes such keen and intelligent interest in the problem. The great mass of exact data available to an officer of the Geological Survey, with the detached position of the organization as a technical bureau, renders particularly valuable opinions from such a source. Mr. Smith is evidently favorable to deep-seated and extensive change, but he approaches the matter mainly from the point-of-view of one who must help meet actual problems as they arise. He favors the separation of surface from mineral rights, "whenever the two estates have values that can be separately utilized," because such separation permits the immediate utilization of the one in present demand without sacrifice of the other. Congress has recognized in recent legislation that it is foolish to give coal of large future value to the man who only wants and can only pay for desert land for agricul-

tural purposes, and that it is equally absurd to prevent present development of the surface, by irrigation or otherwise, because the coal is not yet in demand. We believe the principle of separation of the two values, where there are two values, is sound, and many reasons for so believing are cited by Mr. Smith. The general subject of land law revision can not be discussed adequately in any one paper or editorial. We commend Mr. Smith's arguments to our readers and we desire at this time to emphasize one point only.

The law of the apex has proved troublesome from the first. It is founded on an erroneous conception of the mode of occurrence of ore deposits, and in practical operation it is necessary to buy and hold more land to protect a newly discovered orebody, than would be necessary with square locations. The reason lies in the complexity of the law and the necessity for protection against claims founded on the presence of 'lodes' of both steeper and less steep dip. The case of the Round Mountain Mining Company may be cited as one in point, and difficulties to be faced by anyone undertaking deep development along the Mother Lode in California, as another. The absurdity of regarding the porphyry copper deposits at Bingham, Utah, as 'lodes' such as originally contemplated by the law, is enough to condemn the latter. To all such arguments the common reply has been made that conflicting rights could be adjusted by the courts, and that introduction of the square location would interfere with existing rights. Adjustment by the courts of rights, themselves none too definite, is slow and expensive business, and if no other mineral claim was ever located in the United States, the courts would have enough and to spare of apex litigation for years to come. If, on the other hand, the square location had been adopted ten or twenty years ago, many important districts would have entirely escaped vexatious litigation arising from the extralateral right. The districts yet to be opened should not be denied protection because mistakes have been made in the past. Any change made now could not interfere with any existing right, and it cannot be said too plainly or too often that any revision of the mining law that may be undertaken should be in such terms as to prevent any possible question as to the protection of any accrued interests. This is demanded by the spirit of fairness, and any argument to the contrary is academic. That such a policy accords with the intention of Congress is shown by the fact that when the land withdrawal act was passed, provision was made for confirming any vested rights. For the first time a locator on oil land had protection so long as he continued work in good faith. It is true that a clause which would have operated to confirm all claims, good and bad, was defeated, as it should have been, but legitimate locators were left, as a result of the new law, in a stronger position than ever. It happens that the United States does not recognize a location as a vested interest acquired against itself, and that defence of the possessory right of a locator on public land, as against others seeking to dispossess him, falls to State courts as a part of their work of preserving the public peace. It would be possible, therefore, for the Government to refuse, in case a new law was enacted, to recognize rights acquired by location but not as yet confirmed by patent. We do not believe that this should be, or would be, done, though the point is worth emphasis in order to prevent any possible miscarriage of justice. Revision of the mining law is needed. Old conditions have passed, and to face the new, to continue the development of the West, to secure the highest possible utilization of the great natural resources, radical changes are imperatively demanded. Let the revision be prompt and thorough, but let it protect old rights and define new ones so as to free the industry from unnecessary litigation.

The Mineral Land Laws and Their Defects

By GEORGE OTIS SMITH

*The increasing share which the Geological Survey has been asked to take in the public-land administration by the Interior Department has brought many of the problems connected with the public-land laws more directly to the attention of those charged with the work of this bureau. For over 30 years, however, these problems have interested the Federal geologists, who have had exceptional opportunities for first-hand observation in nearly all the important mining districts of the country, and for almost as long a period the engineers of the Survey have been in touch with the irrigation and power developments in the public-land States. This intimate experience with both field conditions and administrative problems justifies an expression of opinion concerning the land laws, which, it is believed, will be appropriate to this administrative report. To a large extent the principles here presented and the specific provisions advocated have been expressed in memoranda submitted by the Geological Survey to the Secretary of the Interior during the past four years.

PROPOSED AMENDMENT OF PUBLIC-LAND LAWS

The objects to be sought by amendment of the public-land laws are, first, purposeful and economical development of resources for which there is present demand, with retention of such control as may insure against unnecessary waste or excessive charges to the consumer; and, second, the reservation of title in the people of all resources the utilization of which is conjectural or the need of which is not immediate. The means that are essential to the attainment of these objects are, first, the classification of the public lands; second, the separation of surface and mineral rights; and third, the disposition of the lands on terms that will secure the highest use, enforce development, and protect the public interest. Legislation based on these principles will not only secure the positive benefits of immediate utilization, but will also avoid the evils of speculative holdings of lands by fictitious use or by admitted nonuse for the future enjoyment of the unearned increment or of the profits of monopolization. With actual development made a condition of possession, and with land classification and separation of estates made preliminaries of disposition, the present-day utilization by individuals or corporations, and the reservation to the people for future use become at once possible without conflict of interests.

The classification of the public land is essential to the administration of not only such laws as express the principle of separation, but also of those whose purpose is to promote the highest use of the land. Land classification is, first of all, the determination of the best use to which each particular portion of the public domain can be put, and by the organic act of March 3, 1879, this duty was specifically imposed upon the Director of the Geological Survey. Progress now being made in this work is set forth in this report.

Separation of surface and mineral rights might be effected without classification of land by the automatic reservation of all mineral deposits to the United States in every patent issued as a result of non-mineral entry, selection, or purchase. Legislation of this type would possess the merit of simplicity and effectiveness, but the well-known objection to limited patents would with considerable reason be made the basis for the contention that the Government should assume the burden of classifying its land before disposition.

The classification of the public domain is itself an outgrowth of the principle of relative worth, which early found expression in the land laws of this country, in that they provided for the reservation of mineral lands

from disposition for other purposes. The present coal-land law also expresses this principle of relative worth by giving deposits of gold, silver, and copper, priority over coal, and coal, in turn, preference over agricultural values. Such distinctions necessitate land classification based on adequate field examination, and with the classification data at hand the principle of relative worth can be further developed. Wherever the different values of the land conflict, the highest use should prevail, and under legislation that does not oppose the principles of economic law the highest use will prevail.

Under the withdrawal act of June 25, 1910 (Stat. L., Vol. 36, p. 847), classification is made possible in advance of disposition, and disposition can be postponed to await immediate legislation. Fully to accomplish this purpose, for which it was enacted, the withdrawal act itself needs amendment in several particulars. No withdrawal is effective against location or appropriation for minerals other than coal, oil, gas, and phosphate, the apparent intent of the law being to promote the exploration and discovery of metalliferous minerals. However, this exception to the application of the withdrawal law is far too broad, in that it would include such minerals as potash or nitrates, the disposition of which is a matter of no less vital concern to the agricultural interests of the nation than is the proper utilization of the phosphate deposits. So, too, it is true that attempts are being made to claim sand and gravel as minerals excepted by the law and under such contention to secure control of power-sites, even in the face of an executive withdrawal. Connected with this defect in the law is the lack of recognition therein of the principle of relative worth. There is a too-evident opportunity for a gypsum entryman, notwithstanding the fact that the gypsum, by reason of poor quality or lack of transportation facilities, may be worthless commercially, to set up a claim for title to a tract of great prospective value for oil—a tract which is protected from oil entry by an oil withdrawal. Similarly, under the mineral law it is possible to seek title to the walls of a narrow canyon, withdrawn as a power-site, in spite of the great discrepancy between the utterly negligible value of the building stone it contains and the strategic importance of the dam-site.

SEPARATION OF SURFACE AND MINERAL RIGHTS

The first step, both in principle and practice, in any amendment of the land laws, appears to be that of making possible by legislation the separation of surface and mineral rights whenever the two estates have values which can be separately utilized. A notable advance in public-land legislation was the passage of the acts of March 3, 1909 (Stat. L., Vol. 35, p. 844), and June 22, 1910 (Stat. L., Vol. 36, p. 583), which provide that patents issued thereunder grant title to the surface of the land only, and thus permit its agricultural development, while at the same time the United States retains title to the underlying coal deposits. The results have been of undoubted value in permitting homestead and desert-land entries, Carey Act selections, and reclamation-act withdrawals on lands which are withdrawn or classified as coal lands or are known to be valuable for coal.

A similar separation of surface and mineral rights should be extended to all other non-mineral entries, selections, or locations, to include oil, gas, and phosphate lands as well as coal lands, the mineral rights to be reserved to the United States until they can be disposed of most beneficially to the people. For all these lands the need of legislation for the separation indicated is not academic, but actual, since under each class there are already requests for surface patents.

Similar legislation applying the principle of separation

*From annual report as the Director of the United States Geological Survey.

is demanded in order to reserve to the Government the exclusive right to grant easements for the future development of water resources, for either power or irrigation, and at the same time to make provision for grants of surface patents for the agricultural use of the land, or of mineral patents where mining may not interfere with water-power development. During the past year the principle involved in this proposed legislation was recognized by the enactment of an item in the Indian appropriation act which provides for the issuance of limited patents on the shores of Flathead lake, in Montana, where increased storage for power and irrigation may be at some future time found to be advantageous. A further recognition of this principle was given in the water-power bill introduced by Herbert Parsons at the third session of the Sixty-first Congress (H. R. 33000), wherein provision is made for a double use of land leased for water-power utilization and for the reservation in perpetuity to the United States of all rights to future occupancy and use for water-power development on all lands designated by the President. The need of statutory authority for limited patents is most evident in regions where, because of the possibility of future power-development, lands are now withdrawn which possess present value for agricultural use. Provision should be made whereby future power-development will be absolutely insured whenever the value of the lands for such use would exceed their actual agricultural value.

The chief advantage of land withdrawal and classification lies in its essential relation to the principle of proper disposition of the public domain, the real purpose of public-land administration being to insure such reservation or disposal of the people's land as will result in its highest use. The question of amendment of the present laws relating to the disposition of coal, oil, gas, and phosphate deposits on the public domain is recognized as fairly before the public by the specific mention of these minerals in the withdrawal act.

LAW APPLICABLE TO COAL LANDS

The coal-land law is unquestionably the most satisfactory of the present mineral-land laws in that it admits of the placing of an adequate valuation upon the deposits, and in the administration of this law the purpose is not only to base the appraisal price upon the quantity and quality of the coal present and to give consideration to every known physical and commercial factor affecting the value of the deposits, but also to make the selling price approach as nearly as possible the present purchase price of a royalty under a leasehold. Thereby it is intended to permit purchase for immediate development and at the same time to prevent, or at least discourage, purchase for long-time investment or for monopolization. So many factors, however, require consideration that an ideal adjustment of the values is well-nigh unattainable for many, if not for most, coal lands, and on this account a strong argument may be made for support of the lease over the sale system. Under leasehold it would be comparatively easy so to adjust the relationship between ground rental and royalty as to prevent the acquisition of coal deposits until such time as their development should be profitable. On the other hand, it is possible, under the present law, and it is the policy in its administration, to readjust the prices from time to time, either by reduction to encourage development in special cases, or, more commonly, by raising the price on account of increased value due to new discoveries or to changed commercial conditions. The greatest advantage of the lease system to the operator directly, and to the public indirectly, is relief from the large capital outlay now required in the acquisition of the large acreage absolutely necessary for a modern mine. This argument, advanced against the present policy of valuing the public coal-lands at even conservative prices, thus becomes an argument for a leasehold law. Thus contrasting the lease with sale outright to the coal operator, the reduction in capital necessary for original investment must result in reducing the cost of operation to

the mine-owner and thus make possible a correspondingly lower price of coal to the consumer. Hardly less important, moreover, is the better control possible under a lease system, although against the advantage of such control must be weighed the cost of Federal management and the possibilities of inefficient administration or even maladministration.

The present coal-land law, however, has one serious defect, which should be remedied if a leasing law is not enacted. The restriction of area that may legally be acquired to a maximum of 160 acres for an individual and 640 acres for an association is not in accord with good mining practice. The fixed charges on the cost of a modern coal mine, provided with the up-to-date equipment necessary to conserve life and property and to assure maximum recovery, are too high to be assessed against the output of so small a tract, especially if the coal seam is of only moderate thickness. A law designed to promote the practical utilization of coal deposits, where the system contemplates sale or lease, must provide for the holding of a large enough unit to permit the opening and equipment of a modern mine and to warrant its economical operation. Without such provision for commercial operation, too great an advantage is given to the land-grant railroads and large coal companies already in possession of considerable areas of high-grade coal.

LAWS APPLIED TO PHOSPHATE LANDS

The present uncertainty whether the phosphate rock of the public land should be entered under the lode law or under the placer law is conclusive evidence of the need of legislation. As a matter of fact, neither of these laws is more applicable to the acquisition of beds of phosphate-bearing limestone than it would be to that of coal beds. The realization that the phosphate deposits are more extensive than was known or suspected when the Survey geologists began land classification work in Idaho and Wyoming does not lessen but rather increases the urgency for a leasing law which will provide for the utilization of this large supply of mineral fertilizer, so as to meet both present and future needs.

LAW NEEDED FOR OIL AND GAS LANDS

The most urgent need of legislation for the disposition of mineral deposits is in the case of oil and gas. It is most apparent that the placer law, which is none too well adapted to meet modern conditions in mining placer gold, is wholly inadequate if applied to public oil lands, inasmuch as oil is discovered at a late stage in the exploration and development of the land claimed under the law. Thus, large expenditures, extending over several months, if not years, are necessary before any right is acquired against the Government, and during all this time there is no legal protection of the oil prospector against unscrupulous claimants or competitors better backed by capital. The need for remedial oil legislation is somewhat less pressing than it was a year ago, by reason of the passage of the act approved March 2, 1911 (Stat. L., Vol. 36, p. 1015), the effect of which is to validate a class of claims that, although clouded by the construction which the Department was forced to place upon the misfit placer law under which title to oil lands must now be gained, were *bona fide* in that the inception of their development antedated the oil-land withdrawals. This legislation was in accord with the spirit of the withdrawal act, which provides for the protection of equities already established. The need for a better law is, however, imperative, and the legislative action demanded by the situation should not be limited to an attempt to revamp the general placer law, but should consist of the enactment of an altogether new measure especially adapted to provide for the sane and equitable development of this industry in the future. First, the new law should authorize the issue of exploratory permits, granting to individuals or associations the exclusive privilege of occupation, the sole condition of such a grant being diligent and adequate prosecution of development work, measured by the expenditure of fixed sums within certain periods, with possibly the payment of a

small fee to the Government in lieu of such expenditure during the first six months. The issue of this permit should preferably be limited to one to each citizen or association of citizens, although after the lapse or surrender of such a permit the former holder should be allowed to apply for another exploratory permit. In the second place, the law should provide that upon discovery the holder of the permit be given a leasehold title with a royalty varied to meet local and actual conditions. The 'wild-catter' or prospector in unproved country, whether such unproved territory is classified on geologic evidence as oil land or not, should be given special privilege to offset his greater risk. This privilege might take the form of an increased acreage, held both under permit and under lease, or a practical exemption from the payment of royalty, merely a nominal rental being charged under the lease.

The chief advantage that may be urged for the leasehold for oil over a fee-simple title lies in the prevention of monopolization through large holdings. Such large holdings without production would be guarded against by a ground rental sufficiently high to discourage the acquisition of lands except for immediate and continued development, although provision should also be made in the lease for surrender under terms which would protect the Government. This indirect control of development would be preferable to the direct enforcement, by forfeiture, of continuous production, which should be avoided because of the danger of disturbing the delicate equilibrium between supply and demand. Transfers of interest, under either permit or lease, should be permitted because of the absolute necessity in most instances of procuring capital for both drilling and operating an oil well. The law, however, should set forth the purpose of the control of such transfer, which would be to provide protection for the original locators, most of them men of small means, and more especially to insure the prohibition of too large holdings of Government leases by big companies.

LAWS RELATING TO METALLIFEROUS MINERALS

Proposed amendments of the well established laws relating to metalliferous minerals always raise the warmest discussion. With the opinion of mining men in general favoring revision of mining laws of the United States, and with commission after commission appointed by various bodies to suggest improvements, the statutes have remained practically unchanged for nearly forty years, while the geology of ore deposits and the technology of metal mining have made marvelous progress.

The law of the apex has proved more productive of expensive litigation than of economical mining. In many of the more recently established and more progressive mining districts this statute has been made inoperative either by common agreement or by compromise between adjoining owners. Its repeal could not affect established equities under patents already granted, but would render possible more certain property rights in large mining districts, not as yet discovered, where new and valuable claims will be located a hundred years from now. The unit of disposition should be the claim, preferably square, limited on its four sides by vertical planes, and of a size sufficient to allow the miner occupying two contiguous claims to follow the vein or lode to considerable depth, even if its dip is only 45°. Such definition of a mining claim is found practicable in both Mexico and British Columbia, and in the latter country the change from the apex law was effected without trouble or confusion.

The same knowledge of natural conditions that leads to the suggestion of a repeal of the law of the apex forces the further suggestion that discovery of ore in place cannot be made universally a prerequisite to the location of a mining claim. Geologic study of ore deposits has furnished examples in a number of regions where the present law cannot be complied with, although rich deposits exist underground and their extent can be more definitely surmised than in most places where ore is discovered at the surface. To meet such actual conditions, the law should provide for the acquisition of metalliferous mineral land classified as such upon the basis of adequate geologic evi-

dence, whether actual outcrops are present or not.

Most important, perhaps, in any amended mining law would be provision for enforced development, a principle expressed, it is true, in the present law, but not made effective in its workings. A requirement of actual use as a condition of occupancy of mineral land cannot be regarded as either novel or radical. As regards the large acreage of undeveloped land in many mining camps to which patent has already been issued, it is perhaps true that the situation is without relief, unless the Western Australian plan is adopted, whereby the Government steps in and permits mining under a lease, the proceeds of which are assessed, collected, and paid over to the owner. The principle invoked seems to be that no property-owner can rightfully oppose the development of the resources of the State.

In the case of unpatented claims, a remedy should be sought for what has been termed "the paralysis of mining districts," and the rigid requirement of annual assessment work should be made actual and effective by inspection and supervision, in order to put an end to the present procedure of allowing a claim to lie idle for practically two years after its location, not to mention the many localities where claims are held year after year with only perfunctory compliance, or even without any performance of assessment work—a type of local disregard for law that is in striking contrast to the observance accorded to the district customs and regulations of earlier days, whereby the right of possession was made absolutely dependent upon continuous operation.

The remedy, then, for the existing evil of idle mining property must be sought either in the adoption of leasehold, under which the Government can enforce operation, a system which fully attains the desired end of promoting mining development in Australia and New Zealand, according to the report made in 1907 by A. C. Veatch, of this Survey, to the President, or in the thorough revision of the existing system. Radical amendment to the present law would be necessary in order to secure something more nearly approaching equality of opportunity. Some limitation should be put on the number of claims which an individual can locate in each mining district, and the prevention of monopolization would be furthered by the rigid enforcement of assessment development. The record of claims kept by a local official elected by the miners should be reported to the nearest land office in order to furnish the Federal Government with a notice of the intention of the claimant, and thus to initiate the operation of effective inspection, the purpose of which would be to enforce the use and development of mineral land as contemplated in the law.

LEGISLATION REQUIRED FOR WATER-POWER

On the subject of water-power legislation the position of the Geological Survey is essentially that set forth in January of 1911 in a report addressed to the Secretaries of the Interior and of Agriculture by a joint committee representing the two departments. The legislation there outlined would provide for leases of public and reserved lands of the United States valuable for water-power development for a fixed term, not to exceed 50 years, with moderate charges for use and occupancy of the land, revocable only upon breach of conditions or on account of the charge of excessive rates to consumers. These leases should be identical in terms, under whatever department they are granted, with joint and uniform regulations governing all matters relating to water-power development of land belonging to the United States. Provision should also be made for periodic and equitable readjustment of charges, transfer of leases, preferential rights to renewal, and compensation for improvements at the termination of the leasehold. The law should specifically recognize water-power use as dominant, should insure to the lessee undisturbed occupancy of the land needed for such use, and should reserve for future utilization all land believed to possess value for water-power development, these lands to be designated by the President but to be open to other entry, subject to this reserved right wherever separation of the water-power use and other use is possible.

Review of Gold Dredging in 1911

By CHARLES JANIN

ARIZONA

*The Eleanor P. M. Co. is reported as having a gold-dredge in operation in French gulch, but no details are available.

COLORADO

The only place at which gold-dredging is being conducted in Colorado is at Breckenridge, Summit county, where three companies are now operating one dredge each. The first dredges in Breckenridge were of the New Zealand type and were started in 1898; these, and a number of other boats following, proved too light for the ground and were soon shut down. It was not until 1898, when the Reliance dredge was constructed, that any success was met with in gold-dredging in the State. This boat was originally designed as a double-lift dredge, but was afterward entirely reconstructed. The Colorado Gold Dredging Co. is operating a Bueyrus dredge, which is the largest in Summit county. It was built in 1908, and handles from 160,000 to 170,000 cu. yd. per month. During 1910 the dredge handled 1,400,554 cu. yd. at an operating cost of 4.7c. per cu. yd. The dredging season was from March 23 to December 4. This dredge has 42 close-connected buckets of 9½-cu. ft. capacity and is designed to dig 38 ft. below water-level. The profitable gravel is confined to a narrow channel 150 to 200 ft. wide. This company has a dredge now idle in the Blue river. When last in operation, the buckets ran into a hard porphyry dike, and the bucket-line was badly damaged. In French gulch there are boats belonging to two dredging companies, the Reliance and the French Gulch, each operating a 5-ft. dredge. The cost of operating the French Gulch dredge, a Bueyrus boat, which was built in 1908, is stated to be 5½c. per cu. yd., and the monthly capacity 75,000 yd. Operations last through nine months of the year. The Reliance Dredging Co. handles 70,000 cu. yd. per month, and operations are continued throughout the year. The Reliance dredge is an old boat which has been repeatedly overhauled and remodeled. It was originally designed for steam-power, but was changed in 1909 to electric power. Some years ago dredges were operated near Golden, but were unsuccessful, and the machinery was afterward moved to other fields. In Routt county several attempts have been made to dredge different areas, but no dredges are at present operated. A small dredge, with 1½-ft. open-connected buckets, operated for a few months near Hahn's Peak in 1907. The deepest ground was 12 ft., and the best day's work, according to the man in charge, was 1174 yd. in 24 hours, and the coal consumption 4 tons. As coal cost only \$3 per ton, delivered, it is seen that the fuel cost in this instance was not high. The dredge did not pay, however, and was shut down.

The gold won from dredging operations in Colorado has been approximated as follows: 1907, \$36,000; 1908, \$145,000; 1909, \$413,000; 1910, \$344,210; 1911, estimated, \$350,000.

IDAHO

Gold-dredging in Idaho first started in 1891 with the installation of a suction dredge on the Snake river near Minedoka. It was claimed that this boat was successfully operated and that the working cost of handling gravel was

4½c. per cu. yd. However, when the company built a second boat, it was of the bucket-elevator type. This second boat had 5-cu. ft. buckets and an average capacity of 2000 yd. per day over a period of twenty months at a reported cost of 5½c. per cu. yd. It did not prove a profitable enterprise, and it was dismantled, and the machinery moved to Boise Basin. In Boise county a 3½-ft. Risdon dredge was built in 1898 and operated for a number of years until worn out, and since that time a number of successful boats have been built. The Boston & Idaho Gold Dredging Co. put in operation in 1911 a 15-ft. boat built by the Yuba Construction Co. Power is furnished from the company's plant on the Payette river and delivered to the dredge motors, which call for a total of 810 hp. at 2200 volts. This company also operates a 5-ft. Risdon

TYPE OF LIGHT DREDGE TRIED IN OREGON. NOW IDLE.

boat with a capacity of 57,000 cu. yd. per month. This latter boat was built in 1909. One of the most profitable enterprises is said to be that of the Moline Mining Co. at Placerville, operating a 5-ft. Risdon boat. This company formerly operated a steam-shovel plant on the same property. Other dredges have been placed in different parts of Idaho, two near Elk City, and one this last year by the Kirtle Creek Dredging Co., five miles from Solomon, Lemhi county. This is a 9-ft. dredge using electric power. The production for 1911 is expected to show a decided increase over that for 1910, which was, according to the U. S. Geological Survey, \$91,247. Dredging operations in Idaho were described in the *Mining and Scientific Press* for January 1 and July 16, 1910.

Detailed figures of the number of dredges working and the production in recent years are given below:

Year.	Dredges working.	Amount.
1905	3	\$ 34,332
1906	3	39,200
1907	6	74,434
1908	5	77,189
1909	8	101,705
1910	6	91,247
1911 (estimated)		200,000

*For notes of gold-dredging in California, Montana, Alaska, Russia, and the Philippines, see the *Mining and Scientific Press*, January 6.

MONTANA

The operations of the Conrey Placer and Poor Farm companies in Madison county were discussed by Mr. Jennings last week. In Missoula county there are two dredges working, one a Marion dredge at the La Casse placers, and the other, which was started this year on Kennedy creek, a 5-ft. Risdon boat, with steam-power using wood for fuel. During 1909 a dredge was operated for a few weeks near Butte, but has been stopped. The Magpie Development company put a dredge in operation in May 1911 on Magpie gulch, in Lewis and Clark county, about twenty miles from Helena. This dredge is operated by electricity and is said to have cost \$150,000. It was built by the Union Iron Works.

NEVADA

The only dredging operation in Nevada is that of the Federal Mines Co., about 14 miles from Oreana, Humboldt county. This has been discussed by H. G. Walker in the *Engineering and Mining Journal* of June 11, 1911. It is a Risdon boat, equipped with 28 buckets of 5-cu. ft. capacity. The power is furnished by four Doak gas-engines with a total of 196 hp., using distillate as fuel. The depth of the ground ranges from 20 to 30 ft., and contains a considerable number of boulders. The dredge has been shut down after operating but a short time, and it is reported that the boat will be moved to a new location.

OREGON

Gold-dredging in Oregon has never met with any pronounced success. The total production of gold won from dredging operations in the State, does not, so far as can be learned from U. S. Geological Survey records, exceed \$250,000. A number of years ago dredges, both bucket and suction type, were built on the Snake river, and for a while some of them, perhaps, paid operating expenses. One of these, a 5-ft. bucket dredge, was reported as being successful after working over some bars of the river and was moved to Boise Basin, Idaho, where it was shortly afterward shut down. An article written a number of years ago for the *Mining and Scientific Press* by W. M. H. Washburn, gives an interesting account of the gold occurrence on the bars of the Snake river and describes some dredging operations at that time. A pony dredge was operated for a while near Sumpter, but was not a success. It was claimed that the machinery was too light for the character of the ground. A company has started to prepare for a dredge this season on ground near Sumpter. After considerable prospecting the dredge pit was dug 150 ft. square by 12 ft. deep, and it is expected the dredge will be built next year. It is to have 9-ft. buckets and use electric power furnished by the Olive Lake power-plant, and will be the first modern dredge following California methods to be operated in Oregon. In 1905 the Western Mining & Development Co. put in commission a dredge on the south fork of the John Day river. The dredge operated during 1905 and a part of the second season, and was then dismantled. The White-Shelby Hunt dredge, which operated a short time in southern Oregon, was originally built for reclamation work at Grays Harbor, Washington. It was afterward moved to Pleasant Valley, Josephine county, and mounted on wheels. Water interfered with its operation and it was again put on a lull. It was run a short time only; large boulders and difficult digging proved a serious handicap, and the ladder was broken. The dredge was equipped with buckets of 2-cu. ft. capacity and a gasoline engine; it is now idle. The Josephine dredge, near Waldo, Josephine county, was a 4-ft. bucket dredge, using steam and wood fuel, and was owned by an English company. It operated only one season, when, it is claimed, the company got into litigation. Repairs were not kept up, and while in charge of a watchman the dredge sank and has never been recommissioned. Recently there has been a report of another dredge to be built near Waldo, but no definite information is at hand regarding it. The only dredge operated in

Oregon that seems to have made anything over operating profit, and that could be classed as even partly successful, is that of the Champlin Gold Dredging Co. on Foote creek, Jackson county. This is a 5-ft. dredge, operated by electric power. It was operated successfully for several years and during part of the present season, but the bucket-ladder line broke a few weeks ago and the weight of the buckets, about 70 tons, sprang the hull planks and the dredge sank in about 18 ft. of water. It is said that repairs will be made at once; the loss being estimated at \$35,000. While this is the only company whose dredging operations have returned a profit in Oregon, there seems to be no reason why some of the other dredges should not have proved a financial success if they had been properly designed for the ground on which they were placed. It is probable that investigations will be made of Oregon placers in the near future, and if the proposed dredge near Sumpter returns a profit, a number of other dredges of the type that has proved such a success in California will be erected. Gold-dredging in Oregon produced \$34,010 in 1910, according to the U. S. Geological Survey.

SOUTH DAKOTA

During June 1911 the Castle Creek Gold Mining Co. began operating a dredge at Mystic, Pennington county. The dredge was built by the Stearns-Roger Manufacturing Co. of Denver and cost approximately \$95,000. The dredge follows California ideas closely, being built under charge of J. R. Henderson, who was formerly superintendent of the Yuba Construction Co. It is equipped with buckets of 5-cu. ft. capacity and is designed to dig 35 ft. below water-level. In connection with the dredge a power-plant using coal as fuel was built close to the railroad. Electricity is generated at 2000 volts and supplied in motors direct. On account of the power-plant being built to supply one dredge only, the operating costs are expected to be somewhat higher than if several dredges were working. The costs for the first month are given at 5c. per cu. yd. Obviously this figure, while of some interest, has but little real value, and costs over a longer period will be watched with interest.

BRITISH COLUMBIA

Dredging has not so far been a success in British Columbia, and there are no dredges at present working in the Province. Attempts have been made to dredge various areas, and the following account may be of interest. According to the report of the Minister of Mines for 1910: "The various dredging leases on the Fraser river have been amalgamated in one company, the Canada Dredging Co., Ltd., but there has not been any work done by the company up to the end of the year." In 1900 a dredge was erected on the Fraser river, near Lytton. This was built for the Cobbledick Mining Co. by Roby & Co., England. The bucket ladder and tumblers were furnished by Simons Bros., Renfrew, Scotland, and the dredge was constructed under the direction of George Hurst, now manager of the dredging department of the Union Iron Works. The dredge was of the open-connected type, equipped with 5-cu. ft. buckets and designed to dig 35 ft. below the water-level. The dredge was operated several years with varying success, but was finally shut down. It is stated that one of the causes of failure was due to the fact that no tailing stacker had been provided, as it was thought, when the dredge was constructed, that as it was to operate in a running stream, none would be necessary. It was found, however, that at times the tailing piled up and prevented the dredge from even digging its own flotation. No difficulty was encountered from the spring freshets, which some nights, it is said, raised the water-level 15 ft., but experience proved the advisability of keeping the head-lines out of the water. Some years ago two dredges, one having buckets of 3-cu. ft., the other of 7½-cu. ft. capacity, were installed near Atlin, but operated a short time only. Large boulders and an insufficient gold content prevented the operations being a financial success. It is reported that

examinations of several areas on the Fraser river, and elsewhere, have been made this year with a view to building dredges if conditions were favorable, but as yet no definite account has been made public.

VICTORIA, AUSTRALIA

The output from gold-dredges for 1910 was 87,156 oz. In all, 107 dredging plants were in operation, and they treated a total of 19,838,552 cu. yd., with an average recovery of 9c. per cu. yd. The following details of dredges of different classes is taken from the Government report on Victoria: Bucket dredges, 53; pump hydraulic sluice, 46; jet elevator, 8. The best results during the year were obtained by the Tewkesbury Amalgamated Co., operating 5 bucket-dredges ranging in size from 4½ to 5-cu. ft. buckets and dredging a total of 1,553,350 yd., at a yield of approximately 5.6c. per cu. yd. and a cost of 3.8c. per yd. This company paid dividends of £3325 for the year. Considerable attention has been paid of late, in Victoria, to reosiling dredged ground. The latest arrangements in this line have been described in the *Mining and Scientific Press* of April 15, 1911, and a description of hydraulic pump dredge, which has proved so successful in Victoria, was given November 11. The Austral Otis Engineering Co. of South Melbourne reports that during 1911

Kuk San Dong Cyanide Plant

By A. E. DRUCKER

*The method of treatment consists of washing, classifying, and re-concentrating the material as it comes from the dump. The tailing from the concentrator plant is rejected, while the concentrate obtained, containing the bulk of value, is classified, re-ground (all-slimes), and the gold extracted by cyanide agitation and filter-pressing. The plant consists of a concentrator and cyanide annex. The concentrator contains one water supply tank (12 by 12 by 10 ft.), one storage dump bin (22 by 20 by 12 ft.), one 9-in. screw conveyor, one 5 by 3-ft. revolving screen washer and distributor, one 36-in. hydraulic cone classifier, four Callow 6-ft. cone thickeners, and eight No. 5 Wilfley tables. The cyanide annex contains one steel (15 by 12 ft.) stock cyanide solution tank, one concentrate storage bin (22 by 10 by 12 ft.), two 6-in. bucket elevators, one 6-in. screw conveyor, one 4 by 16-ft. tube-mill, two 3-in. Morris centrifugal sand-pumps, two hydraulic 36-in. cone classifiers, two 6-ft. Callow cone thickeners, four Pachuca steel agitators (8 by 30 ft.), two steel sand-clarifying tanks (10 by 6 ft.), four zinc-precipitation boxes (36 by 30 in. by 12 ft.), two steel cyanide-solution sumps (15 by 12 ft.), two Morris 2-in. centrifugal solution-pumps, one Montegu pressure tank, one Dehne (24-frame) filter-press, one vacuum-pump, and gold precipitate filter-box. The power-plant consists of one 90-hp. steam-engine, one air-compressor (300 cu. ft. per min.), and one Fraser & Chalmers (60 in.) steam boiler. The foregoing is a full description of the plant. It occupies a space 30 by 140 ft., with an engine and boiler room annex. The tube-mill, pump, engine, and Wilfleys are set on concrete foundations. It was necessary to put in four stone retaining walls.

Up to August 1, 1911, the plant had a very irregular run, due chiefly to trouble with the sand-pumps, Pachuca agitators, steam-engine, and inexperienced native help. The Pachuca agitators were connected in series and fitted with battle cylinders so as to use the continuous agitation and decantation method which has proved an advantage in the modern plants of Mexico. This arrangement has proved a failure in our case, neither were we able to obtain a satisfactory circulation of the pulp, nor clear solutions to the clarifier tanks and zinc-boxes. This has been the most serious trouble and has prevented the getting through of a satisfactory amount of concentrate, also interfering largely with precipitation in the zinc-boxes. We have, however, at the present time overcome these defects by a different arrangement.

It must be remembered that in no other place has the attempt been made to re-treat an old oxidized concentrate cyanide tailing dump by the cyanide process, and in no case have we been able to profit by the experience of others on a similar proposition. Therefore we have had to work out a special treatment of our own. The plant is now treating 60 tons per day and will be brought up to 80 tons capacity per day, that which it was originally intended to treat. During the past we have been running through dump that only assays \$2.56 per ton, so as to prevent losses until things were made right. Our new plant at Taracol will reap the benefit of our experience at Kuk San Dong. The assays and bullion returns so far show that we are able to obtain the following results:

- Dump heads, \$2.56 per ton (average heads for total dump, about \$7).
- Gold extraction by concentration, 79% (value contained in concentrate).
- Gold extraction by cyanidation, 73% (value extracted from concentrate).
- Total bullion extracted from \$2.56 heads, 58 per cent.

FIVE-FOOT DREDGE, FRASER RIVER, BRITISH COLUMBIA.

dredge construction was almost entirely comprised of the removal of dredging plants from old sites to others nearby, and that there is little opportunity for new plants in Victoria and the Commonwealth generally, as dredging has of recent years been greatly restricted, and also as there are in existence so many plants, which were built during the dredging boom, and put on unprofitable areas.

The following table, giving the results of dredge mining in Victoria, has been adapted from the report for 1910:

Year	No. of companies working	Total cubic yards hauled	Yield in ounces	Average yield, cents per cubic yard	Total acres worked	Yield per acre, oz.
1905	82	13,450,945	72,926	11.1	479.5	152.1
1906	125	17,307,277	85,271	10.1	628.5	135.6
1907	133	20,199,892	97,821	10.1	739.0	132.3
1908	123	20,546,346	104,167	10.3	777.2	134.0
1909	111	19,979,131	88,339	9.0	737.7	120.0
1910	107	19,838,552	87,156	9.0	698.0	124.8
1910-1911*	..	149,209,093	726,431	10.1	5187.0	140.0
Prior to 1910*		+14,000,000	90,525	...	432.0	210.5
		+163,209,093	816,959		5617.0	145.4

*From report of the Oriental Con. M. Company.

New Zealand and Nevada Mining Methods Compared

By F. C. BROWN

Having recently spent a short time at the comparatively new mining districts of Tonopah and Goldfield, Nevada, I have been thinking it might be of interest to some of your readers to have a few comparisons between methods and conditions existing there and those in New Zealand, where I have been engaged in mining during the past fifteen years. The actual mining methods at Tonopah and Goldfield are somewhat difficult to compare with those in use in New Zealand, as the conditions in the two places are different. In the former district there is very little water with which to contend, so the mines are not equipped with the huge pumps which are a feature of the Waihi, Karangahake, and Thames districts in New Zealand. All pumps and other machinery in the mines and mills at Tonopah and Goldfield are operated by electric power obtained from about 100 miles away, while in New Zealand, although water power is available for generating electricity within a reasonable distance of the mines, power is chiefly produced by means of steam-engines, steam-turbines, and producer-gas engines. The Waihi mine is now preparing to produce some 6000 hp. from water power sixty miles from the mines, with the object of driving most of its machinery by electricity.

At Tonopah and Goldfield the development work in the mines is done almost entirely by the wages system, and there is practically no hand-drilling of holes, the heavy work in drifts being done by piston machines, and the lighter work in the stopes and raises by the hammer machines. In most districts in New Zealand the bulk of underground work is done on the contract system, driving, raising, and sinking at so much per foot, and stoping, usually by the ton of ore broken. The contract specifications provide for the contractors doing the whole work to the satisfaction of the underground manager, and all necessary material, such as explosives, candles, and the like, are provided by the company, but charged up to the contractor at about cost price; the company also supplies the drilling machines and power to operate them. As a rule, a contract is taken by a party of men, and this party, unless large enough to fill the terms of the contract as regards the number of men employed, engages wage-workers to make up the required number. Such wage-workers are invariably paid higher wages than the ruling rate paid by the companies. The wages for miners are \$2.15 per day of 8 hours, a week's work being 45 hours, provision being made for a short half holiday on Saturday. A week of 45 hours is classed as 6 full working days on the pay-sheets. The day shift commences at 8 a.m. and the men stop work at 4 p.m., being allowed half an hour at noon for lunch. Men working in the mills are on duty for the full 8 hours and have no half holiday on Saturday. Contractors, on an average, make about \$3 per day, and they pay their wage-men at least \$2.50 per day. Extra good parties of contractors make up to \$5 per day for each man.

I understand the wages for miners at Tonopah and Goldfield are \$4 per day and \$3.75 for shovelers, and I should judge that the miner in New Zealand who can make \$3 is the better off, as living there is cheaper and the general conditions better. A peculiar feature in New Zealand is the closing of the mines for about a two weeks' holiday at Christmas. It must be borne in mind that Christmas comes in mid-summer there and is a great holiday season throughout the whole country.

In New Zealand there is now no Sunday work at the mines or mills, except such work as pumping in the mines and the running of agitators in the mills, and necessary repair work. This work is provided for by special permits issued by the Government Mining Inspector. When this law was under discussion some years ago, all the mining companies were against it, and all the old arguments, such as decreased output from the mills and consequently less employment for the miners, were brought to bear upon the

case, but after the law had been in operation for some years there were few, if any, who wanted to return to old conditions. Outside of the religious and physical aspects which indicate that a rest-day in seven is necessary for the well-being of man, the closing of mills on Sunday brings other advantages, as repairs and alterations can be effected while the machinery is at a standstill, instead of having the men working amidst swiftly moving belts and rapidly revolving pulleys, shafts, and fly-wheels—all with such a terrific noise everywhere that it is even difficult for a foreman to give correct instructions. My experience is that, after the passing of the Sunday-rest law, the machinery in mills was better looked after than it was before.

At the mines and also the mills in Tonopah and Goldfield there is more effort in the direction of doing away with hand labor than in New Zealand. In the former places all the mining steel is sharpened by drill-sharpening machines, while in New Zealand this work is still done by hand, even at the large mines. The handling of the ore, especially the crushing of it preparatory to putting it in the ore-bins behind the stamps, is done in a far more practical manner than in New Zealand, and I notice the Goldfield Consolidated uses 50-ton cars for a comparatively short haul from the mines to the mill, while in New Zealand the usual practice in hauling ore even over distances of five miles, is to use a large number of small cars, holding 3 to 4 tons each.

With regard to milling methods, it is difficult to make comparisons, as each class of ore requires its own special process or combination of processes, and even in the case of two adjoining mines a variation of processes is sometimes necessary. In New Zealand the tendency is to go in for all-sliming, and stamps followed by tube-mills are the favorite combination for reducing the ore. Crushing in cyanide solution is being introduced there and is giving satisfactory results. When concentration is necessary, the concentrate is treated in a separate plant, the process being grinding to a very fine slime and cyanidation of this slime. The slime is treated by air-agitation, usually in Pachuca tanks, and filtered in vacuum-filters, the solutions being precipitated on zinc shavings. The zinc-dust process has not gained a footing there, although it has been tried by some of the large companies. Tube-mill practice in New Zealand seems to me more advanced than at Tonopah and Goldfield, and this is no doubt due to the fact that tube-mills have been used in New Zealand since 1903, while at Tonopah and Goldfield they are a more recent innovation.

Most vacuum-filter plants in New Zealand are of the type which requires the filter leaves or frames to be lifted from the sludge and wash tanks, while at Tonopah and Goldfield the stationary filter-frame type seems to be the favorite. Both types do good work if properly erected and attended.

In New Zealand all workers in or about mines or mills work under an industrial agreement as regards wages, hours, and some other conditions, this being one of the provisions of the Arbitration Act, the object of which is to prevent strikes by bringing the employer and worker together to discuss any matters causing friction which may arise. These agreements are entered into by the mining companies of the district as one, party, and the workers, represented by their unions, as the other party, and are usually for a period of three years. The Arbitration Act has now worked well for a number of years, but it has still to go through the test of a general labor upheaval, when labor pits itself against capital for a reason or reasons often difficult to define. Even if the act should fail in a period of great stress, it has already, in my opinion, proved of great benefit to both the employer and worker by bringing them together to discuss the general

conditions of labor, both sides being called upon to present its views of the questions at issue.

In Tonopah and Goldfield a deduction is made from the men's wages for the medical fund, a worker being entitled to free hospital treatment in case of accident or sickness. In New Zealand compensation for accident is provided for by the Workers' Compensation Act, under which a schedule sets forth the claims that can be made for the various kinds of injuries, temporary or permanent disablement, loss of health, or death. During disablement the worker receives half pay. Loss of life is assessed at about \$2000, the money going to those who were dependent upon the deceased for their support. One of the great benefits of this act is that the worker, instead of having to fight his claim through the courts and risk the fees of unscrupulous lawyers, receives full compensation according to the schedule. If a company does not like to carry its own risk under this act, it can take out an insurance policy, either in the Government Insurance Department or in a private insurance company, the procedure being to pay a premium rate depending upon the degree of hazard in the occupation. The premium is paid for a year in advance and is based on the estimated wages for the year, adjustment being made at the end of the year.

I was familiar with mining conditions in this country when I left for New Zealand fifteen years ago, and I now notice a great improvement in the way men are cared for and treated by their employers, and it is to be sincerely hoped that mining companies will see the wisdom of continuing to use every effort in this direction.

German Mining in 1911

German mining is for the most part concerned with coal, iron, and potash. Coal production was unusually large all through the year 1911, and every month up to and including October, with relatively slight exceptions, the production has been greater, month by month, than in any year since 1907. As this increase has been steady, it may be assumed that most of the coal has gone into industry, largely, of course, by way of the coking ovens. The improvement includes brown coal, and the returns for coke show that larger quantities than usual have been used for metallurgy. The total quantity of coal produced in the German Zollverein during the first 10 months of the year was 133,470,434 metric tons. This compares with 126,030,092 tons in the corresponding 10 months of 1910. The figures for lignite were 60,292,946 tons, against 56,284,894 tons. The coke produced in the corresponding periods named was 20,818,326 tons and 19,393,499 tons.

Returns for iron ore production are not available. Since pig iron production keeps mounting up with a record output every month, the assumption is safe that the production of iron ore has been likewise growing. Import returns covering iron ore from foreign countries, such as Scandinavia and Spain, may, however, show that foreign countries have supplied the excess ore. The production of pig iron for the first 11 months of 1911 was 14,156,586 tons. This is almost as large as the total for 1910, and is larger than the total for any other preceding year back to the year 1905. It may be observed that besides Spain and Scandinavia, Germany proposes to draw largely on French iron-ore fields. One of the largest German houses has erected works in Normandy, where it will even engage in smelting. Brittany, too, will be the scene of German enterprise. There are in Normandy already 22 iron ore works, of which 5 at least are of considerable importance, and in Brittany there are 7 in process of development. As these fields are not conveniently situated for smelting purposes, it may be taken for granted that it is intended to export the ore. It is even stated that the house of Fried. Krupp has made a contract with a number of Normandy iron-ore producers for as much as 12,000,000 tons of ore to be shipped to Rheinhausen by way of Caen.

But the factor in German mining which has stood out

most boldly this year, as last, has been the development of the potash deposits in the Western districts. This has been thrown into sharp relief by reason of the contract disputes with American buyers, and the international embroglio which resulted. The Germans are in no way perturbed at the reports of the discovery of potash in America, but this must be read strictly in the present tense. When the report was first sent round, they were very nervous indeed; so much so, that a learned professor at Heidelberg felt constrained to confess to his fellow countrymen that Germany need not look for a permanent monopoly of the potash business, since geologists were well aware of the existence of large reserves in other countries which had only to be exposed to bring enterprising contractors to the field to develop them. Meantime it is known that the exploitation of the potash fields of Germany has been carried on very actively, and the value of the products exported, particularly, has reached an extremely satisfactory level. But it is rather with the proximate future than with the present that the chief interest lies. An effect of the new potash law, particularly the features guaranteeing a market for the product of almost any potash field fairly exploited, has been to bring a large number of companies to the fore that have undertaken to develop and exploit fields hitherto left untouched. The effect of that on the potash mining industry has been somewhat remarkable. Germany is not unacquainted with the principle of concentration in her industries; but when the company promoter swooped down on potash and floated company after company in order to take advantage of the new law, the existing old fashioned potash concerns felt compelled to take steps in self-protection and adopted a policy of amalgamation or concentration which has profoundly affected the whole potash situation. Companies that were large before have by absorption become larger still, and insignificant or poorly paying companies, have acquired importance by reason of alliance with great concerns that have found it worth while to absorb them. The near future therefore will see a tremendous extension of potash production in Germany. The old works are equipping themselves to compete in this respect with the new houses; and unless, as is urged by some, the Government intervenes with fresh laws to limit the production, the country is within easy reach of a feverish activity in the potash fields that may well result in a glut. Naturally as the world calls for more fertilizers the demand will at all events to some extent, if not entirely, keep abreast of the growing supplies. But the time is approaching when the new companies will be starting exploitation in battalions and the great quantity of potash which they will bring into the market must almost inevitably produce a potash crisis. But that time is not yet. Perhaps the Government will be able to take measures to regulate the business in proportion to the world's needs. This is a step that has been taken with great success—for example, in the neighboring country of Russia with its sugar business—and as Germany is following in the same direction in the matter of nationalizing industries, as shown by the interest her Government is taking in the coal and potash mining industries, it is fair to assume that no serious calamity will be allowed to take place for want of regulation.

The petroleum production, which was 110,996 metrical tons in 1910, undoubtedly amounted to somewhat more in 1911, as fresh wells have been opened. Other mining industries exploited are copper, zinc, pyrite, lead, manganese, and salt, but the returns are not available on which to estimate the work done this year. As the German industry in 1911 has been remarkably successful, there can be little doubt that in all these items progress will be reported as compared with 1910.

THE estimated December production of the Goldfield Consolidated Mines Co. was 29,127 tons of ore from which the gross recovery was \$700,000. The operating expenses were \$240,000 (including \$42,000 for construction work), corresponding to a net operating profit for the month of \$460,000.

Review of Lake Superior Copper Mining in 1911

By ROBERT H. MAURER

Dividend disbursements by Michigan copper-mining companies during the past year and total payments of all companies for all years of which there is any record is presented herewith:

Companies.	1911.	1910.	Total to date.
Ahmeek	\$ 100,000	\$ 100,000
Atlantic	990,000
Calumet & Hecla....	2,400,000	2,900,000	114,900,000
Central	2,130,000
Cliff	2,518,620
Copper Falls	100,000

The non-dividend payers are many, and among them are few that give promise of early dividends. The Isle Royale and the Allouez would seem to be exceptions. Both are operating with some profit to themselves, and each is rounding into shape for heavier production, and dividends eventually. The status of Franklin has changed wonderfully during the year under efficient management, and this company will make good. The same may be said for the Lake and Hancock. The others are coming along more slowly, with varying degrees of promise.

Considerable attention was directed in 1911 to the exploitation of new territory, though not to the extent observed in 1910. This work has on the North Range added materially to the known mineral resources of the district and opens a wide strip of possibilities along the eastern edge of this range. The disclosures in the St. Louis and New Baltic acreages are most important. The South Range was quite thoroughly explored in the preceding year and continues to receive its full share of attention. More than 30 companies were actively engaged on both ranges seeking workable copper deposits or developing deposits already opened, and nearly \$2,000,000 was required, in amounts varying from \$100,000 to \$300,000, to meet the cost of this work during the past year. Eight companies active in the preceding year suspended operations indefinitely for various reasons.

The number of workers employed in the various branches of the industry was smaller than in the preceding year and is now around 18,000, compared with 19,000 a year ago and 21,000 employed in the three counties in 1907. Fully 15,000 find employment in Houghton county. The surplus of labor is quite evident, despite the great numbers that have gone to other fields. Attempts to unionize local labor are not very successful, and though the Western Federation of Labor has established a foothold and maintains local headquarters, its efforts are not well received.

The fear in the minds of many that the Lake Superior district has seen its palmy days with the passing of the Calumet conglomerate lode, now less than 20 years removed, is a mistaken one. Less than one-fourth of the known mineral-bearing area has been touched, and though

there may never be another deposit such as was the Calumet conglomerate, there is in the area under development at different points a demonstrated tonnage far greater in the aggregate than was contained in this famous deposit. The porphyry bugaboo also has created a most unpleasant fear that the Lake Superior vein mines would soon be a thing of the past. This fear is brother to the fear that in the late '90s possessed so many of our good people when the Butte mines were expected to put the local producers on the shelf. There is not a sign of the grass growing on the streets that the mind's eye of that period pictured deserted, and the Lake mines will be doing business years after the present porphyry deposits have become exhausted. A brief resumé of what the Lake Superior companies accomplished during the past year and what can be expected in the future, follows.

The Calumet & Hecla Mining Co., with probably less than 20 years of life remaining in the conglomerate lode, is concerned chiefly with the development of the Osceola lode mine and with the development of a number of other mines on this and other formations in which it has large shareholdings. The conglomerate bed has been a most profitable source of production and will continue to be to the end of its life, though declining values have materially affected profits. Openings have been kept well ahead of immediate requirements, and much good ground is being developed in places long thought to be without value. Particularly is this true of the Black Hills portion of the mine. The conglomerate is supplying around 80% of the Calumet production, about 2,000,000 tons of ore, averaging 30 lb. of fine copper, annually. There remain approximately 30,000,000 tons unmined. In the Osceola lode the company has a low-grade property easily capable of supplying 1,000,000 tons annually, of an average copper content of about 15 lb. of fine copper. A tonnage standing close to 16,000,000 tons has been placed in sight, out of a total possible tonnage estimated roughly at 40,000,000 tons. A limited amount of work is also in progress in the Kearsarge lode with results not altogether satisfactory. Many economies were introduced during the year in the effort to achieve 'dollar rock', and though such a figure may never be reached, material reductions in the cost of breaking ground have resulted. Early in the year the company became involved in litigation growing out of its proposal to merge the several so-called Calumet subsidiaries, and is to some extent yet involved, but has abandoned its merger plans and will continue to operate the various companies independently. The great savings that would undoubtedly have resulted in their operation under the plans proposed, have by the opposition of protesting shareholders, thus become only savings that might have been made. In addition to the output secured from the Osceola and Calumet conglomerate lodes, the company, through its ownership in the subsidiary companies, controls upward of 57,000,000 lb. fine copper, giving a total output of well over 130,000,000 lb. fine copper annually, or approximately 60% of the entire output of the Lake Superior district.

The Copper Range Consolidated is not directly engaged in mining, but is a securities-holding company controlling and directing the operation of the Baltic, Champion, Trimountain, and Atlantic mines and the Copper Range railroad. It is none the less a considerable factor in the Lake Superior output contributing approximately 20% of the total production of the district. The mines operated by the company yielded approximately 41,000,000 lb. fine copper, a decrease of but 2% from the output of the preceding year. In this production the St. Mary's company has an equity equal to about 9,000,000 lb., being one-half of the output of the Champion mine, owned jointly by these companies, leaving the Consolidated a

net production of about 32,000,000 lb. The company's position was further strengthened during the year by the acquisition of the Atlantic property, which development has shown to be not wholly without promise despite rather negative results obtained in the past under the former management. No work has been done in this property by the new owners. The Baltic and Champion mines are the mainstay of the combination and show no appreciable changes from year to year. Both are opened well ahead of immediate requirements, and both are yet in their infancy. The Trimountain mine has improved wonderfully during the year, is earning a small profit, and promises soon to take equal footing with its big neighbors, the Champion and the Baltic. Production increased more than 25% over the previous year.

The Osceola Consolidated Mining Co., fourth in point of production, ranks third in the list of dividend payers of the district with a disbursement of \$721,125. Production was smaller by about 1,000,000 lb. compared with that of the preceding year and is about 20% under normal, due principally to the loss of production from the Osceola Branch, which was shut down nearly two years

The Ahmeek is all progress and coming along faster every year. Production increased fully 25%, costs were further reduced to a figure close to 7¹/₂¢, and there is no other producer with a brighter future before it. Late in the year the company paid its initial dividend of \$100,000 and just before the close declared a second dividend of \$150,000, payable early in the new year, with promise of dividends quarterly thereafter. Development in the new north shafts disclosed a continuation of the same excellent copper ore opened in the older and deeper south shafts, and another year will put the mine in position to produce upward of 20,000,000 lb. fine copper.

The Wolverine Copper Mining Co. reports an average production and dividends slightly reduced, the year's disbursements amounting to \$540,000, as against \$600,000 last year. Production is secured entirely from the mine on the Kearsarge lode and promises to hold for another ten years, after which the company will have to look elsewhere for its copper. A number of promising copper-bearing lodes traverse the property, and these are being explored. The Osceola lode has been opened by shafts and drifts to a depth of 300 ft., and is generally without

Each rectangle is a township, six miles square.

THE COPPER MINES OF THE LAKE SUPERIOR REGION.

ago and remains idle. The output was approximately 15,300,000 lb. fine copper. The Kearsarge North and South branches were operated without interruption, and in the North Branch resulted in the development of considerable productive ground in the older workings. The South Branch has become a stoping mine and fully developed with about 2,000,000 tons of ore remaining unmined, and will probably become exhausted within another ten years. The North Branch is good for 40 years to come. The Osceola, too, is striving for 'dollar rock', and its efforts have come closer to realization than has any other mine in the district. The cost of mining, transportation, and milling a ton of rock during the past year will probably average less than \$1.20 and may even reach \$1.10. The ability to show such remarkably low operating costs is in part due to the favorable physical condition of the South Kearsarge Branch, but is withal an achievement that fairly radiates good management.

The Quincy Mining Co., when final figures are in, will report a production probably 5% below that of the preceding year. The dividends, too, were reduced, and for the year totaled \$140,000, compared with \$550,000 in the preceding year. The mine is old and deep in the south end, in which operations were begun, but is being reinforced by the north territory, in which three shafts are being steadily sunk. The Quincy is no longer the rich mine it once was, and ore values here, as in all other Lake Superior mines, have declined materially with depth. The present yield will range 14 and 16 lb. fine copper per ton of ore mined, and will probably average slightly better than 15 pounds.

The exploratory work to the eastward of this and the Kearsarge lodes is showing more encouragement. A promising copper-bearing amygdaloid was cut in the horizon of one of the Old Colony lodes and will probably be followed by other beds with the further extension of the cross-cut now driving in that territory, and is expected to give the company a mine in that section.

The Mohawk Mining Co. is the champion low-grade producer of the district, and its ability to wring profits from the treatment of copper-bearing rock yielding less than 15 lb. fine copper per ton of rock reflects great credit on the management. Earnings were at the rate of \$150,000, compared with \$200,000 in the previous year. The north and poorer end of the property has shown some improvement under development, but it is in the south end that the future of the company lies. This end shows marked betterment at depth and, already a considerable factor in the output of the mine, is yielding a grade of rock probably 25% richer than is that yielded by the older workings on the north. Five shafts are sinking steadily and one has been permanently bottomed. The No. 6 shaft, sunk on the extreme south end of the property, is down around 700 ft. in depth, with lateral extensions on several levels breasted in copper ground of exceptional richness and which appears to improve with depth.

The Tamarack is seemingly hopeless. It is a deep mine and the cost of production is high. Little encouragement is had from the year's operations, which were conducted for the most part in ground of known worth and with little regard for the creation of reserves. Work in the Osceola lode has ceased entirely. The working force was

greatly reduced in an effort to produce copper at a profit. Production declined more than 50% until late in the year, and near the close was again normal, the year's output reaching 7,500,000, as against 11,060,000 lb. in the preceding year.

The Isle Royale, Allouez, and Superior companies may be grouped in one class. All report average productions made at a small profit to themselves and, excepting possibly Superior, have become mines of demonstrated worth. Isle Royale is the largest producer of the trio. Production holds steadily around 7,000,000 lb. fine copper annually, and promises to increase materially as a result of development now in progress. Activity is centred in the development of the Isle Royale lode, in which the company now has four producing shafts, with prospects of two more to follow. The property is one of great potential worth, and, though a limited amount of exploratory work in the Baltic lode failed to reveal copper in commercial quantities, the more recent developments in the Houghton acreage adjoining makes ultimate success reasonably certain. Allouez is giving full attention to the development of the Kearsarge lode with good results generally, and today is nearer dividends than is any other of a number of likely prospects among the non-dividend payers of this district. The mine is easily capable of producing 10,000,000 lb. fine copper annually at a cost of not to exceed 10c. per lb. following completion of improvements now under way at the north shaft, and an output close to this figure is predicted for the new year. Superior is capable of greatly increased production. While development in the north shaft is adding to the reserve at a satisfactory rate, similar work in the south shaft is discouraging. The company is just about breaking even on present price of the metal.

In quite another class are the Lake, Franklin, Hancock, Mass, Centennial, and Winona. The Lake is an unknown quantity, with possibilities on the Lake lode rather limited. Its unexplored territory measures acres in extent. Commendable progress was made in the development of the Lake lode and in fitting the property for regular production, and a small though rich mine has resulted. Production is expected to begin in early summer. The Franklin has turned the corner after years of discouraging work and is going to make one of the biggest mines in this district. Development is confined to the Pewabic lode, in which two shafts have been sunk and provision made for three more. Both mill and mine were overhauled in a most thorough manner with the one idea of economy. The new year will see the rate of production trebled. The Hancock centred attention in shaft work and has attained a depth of 3100 ft., with prospects of reaching the Quincy-Pewabic lode within another 400 ft. Several promising veins were opened in the course of sinking in this shaft and will add materially to the mineral resources in this acreage. Considerable work was also done in the Hancock lode, and a mill-test of short duration gave returns of slightly more than 18 lb. fine copper from the material treated. It is quite unlikely that Hancock will figure as a producer in any considerable quantity for several years to come. Mass is in the making. The shafts are being equipped for heavy duty, and the reserve is growing at a satisfactory rate. The mine promises soon to do better than merely get a new dollar for an old one. Development is in progress in the Evergreen and Butler lodes, and is generally encouraging. The mine is in better physical condition than it has been in many years. Centennial confined activity to the development of the South Kearsarge underlay and appears to have turned the corner. The north laterals at depth are continuously in excellent copper ground. Winona is making haste slowly. A consolidation was effected with the King Phillip adjoining, and the two properties are being developed as one. Production was begun upon the completion of the stamp-mill about the middle of the year. A large tonnage of low-grade material has been developed, and the mine is easily capable of doubling the present rate of production.

Of the greater number of companies engaged in explor-

atory work among which Victoria, though yielding a regular production may be included, lack of space forbids more than mention. Victoria is obtaining just enough encouragement to induce further work. The best in this division are Laurium, Indiana, Algoma, Houghton, St. Louis, Adventure, Ojibway, Oneco, and New Baltic. All seem to have found copper deposits of promise and are now engaged in exploratory work. Wyandot has nothing in sight, but has hopes. Others have passed this stage and found their several discoveries wanting. Among them are the Keweenaw, Gratiot, La Salle, and Seneca. A few others are seeking more encouragement before making the more thorough investigation that only underground openings can give, in which category are Mayflower, Old Colony, Bohemia, North Lake, and New Arcadian. South Lake has found a promising deposit, but lacks funds with which to carry on development. Section Twelve is in the same class. Somewhere new mines are undoubtedly in the making.

Work in the Snake Creek Tunnel

The Snake Creek drainage and transportation tunnel in Utah, projected and controlled by stockholders in the Daly-Judge M. Co., has been driven about 4100 ft., and is to be 15,000 ft. in length when completed. Its portal is in Snake Creek canyon, on the Heber City side of the Wasatch range, being eight miles from that town. It will cut the crest of the range at a depth of over 3000 ft., but the depth to be attained in Daly-Judge ground, on the Park City side, will be close to 2100 ft. The dimensions are 9 by 6½ ft. in the clear, with a concave water channel, having a top width of 4 ft. and a depth of 3½ ft.; this channel is on the right-hand side of the tunnel, the left-hand side having a solid roadbed for trackage designed for loaded cars. A track is to be laid over the waterway for empty cars. The present flow of water from the tunnel is about 2250 gal. per minute. The range of costs thus far incurred in driving is \$25 to \$30 per foot.

About 300 ft. of swelling and caving ground was passed through a distance of about 2000 ft. from the portal, and this proved to be so troublesome that this part of the tunnel was first timbered, then built up with reinforced concrete. The concrete work is supported by an arch formed by 50-lb. steel rails set in pairs. The rails are heated and so bent that when two are joined together by fishplates they form an oval, and sets of these are placed 4 ft. apart inside the timbers in the tunnel, the lower or small end of the oval-shaped frame being placed downward and buried in concrete below the track level. This steel frame is reinforced at the top of the arch by a second rail. The spaces next to the timbers are filled with concrete, and extending from one set of rails to the next is a triangular-mesh wire screen, weight 109 lb. to 100 sq. ft., held in cement. The arch has a height of 7 ft. 1½ in. above the tracks, and has a width at track level of 9 ft. 6 in. The track is laid on 8 by 8-in. timbers, 4 ft. apart. This special work is now in progress. It is being performed at the expense of the Snake Creek Tunnel & Transportation Co., under general direction of G. W. Lambourne, manager for the Daly-Judge company, though the tunnel proper is being driven by Free & Taylor, under contract. O. N. Friendly, engineer for the Daly-Judge company, has direct supervision of the tunnel work as a whole.

Coal in Montana

According to the annual report of State coal mine inspector, J. B. McDermott, one man was killed during the past year for every 224,107 tons of coal produced in Montana, and one man was injured for every 58,268 tons produced. There was one fatal accident for every 290 men employed, and one serious accident for every 76 men employed. The coal production for the past year amounted to 2,913,397 tons, as against 2,970,246 tons in 1910. A total of 3776 men are engaged in coal mining, and the mine value of this year's product is given at \$4,903,621.

Wyoming Mineral Industry in 1911

By ALBERT C. BOYLE, Jr.

During the year 1911 mining operations in Wyoming as a whole were quiet. Certain districts have been characterized by continuous development, most of which has resulted in opening bodies of good ore. Considerable attention has been paid to the development of new territory which has added much to the known mineral resources of the State. In gold-mining, the greatest amount of work has been done in the South Pass district, where the Buck Mining Co. has erected a small mill. Prospecting and development have been carried on also in the Medicine Bow and Bear Lodge mountains. Here gold is found in quartz veins and in ideal condition for cyanide treatment, and several steam dredges are operating. Copper ores are found in every county of the State, and consist almost wholly of altered sulphides. In some localities the oxidized and carbonated ores have accumulated in great masses. Systematic sampling shows some of these masses to contain 14% copper. At the present time the deposits are situated far from transportation facilities, and are therefore of no importance commercially, but are of interest as possible sources of copper. One great drawback to the State is that a large portion is arid, and prospectors, unless specially well equipped, cannot penetrate safely into the greater portion. Consequently a large part is absolutely unexplored.

Within recent years Wyoming has advanced to the front as an asbestos-producing State. Great activity has been in the Casper district, where asbestos of excellent quality occurs in great quantity. Throughout the State this valuable mineral is found, but at present this is the only known locality where chrysotile is in such associations as warrant commercial extraction. The Consolidated Asbestos Co. has erected a completely equipped fiberizing mill and is now placing on the market excellent products. The long fibres

are especially well suited for spinning and weaving, while the shorter stock is manufactured into board, plaster, and paper. There is good reason for believing that Wyoming will become an important factor in the supply of this product. The management reports a very successful year from the point of view of asbestos production.

In iron-ore mining the chief operations have centred around the Sunrise district, where ores of excellent quality exist. The mines are near a main railroad line, and at present the products are shipped mainly to Colorado. The actual tonnage is not known at the time of this writing, but it is safe to say that 1911 has been the banner year in the iron-mining industry. Many other localities are known within the State where iron ore deposits of high grade exist. These will be of greater importance as transportation facilities are made better.

The past year has witnessed marked progress in the oil-fields. Pipe-lines, storage tanks, and refineries are now available in many of them. New fields have been drilled, and while little is definitely known regarding many of the smaller fields, it is generally understood that the productive oil area has been greatly increased. The smaller wells are capable of producing from 100 to 200 bbl. per day, and it is stated on good authority that some wells are now producing 5000 bbl. per day. The oil found is of excellent quality, and, with few exceptions, has a paraffine base. The greater part of the oil produced is shipped out of the State, but there is considerable local consumption also. The Leroy, Spring Valley, and Byron fields find ready market for their products in Utah and the West. The reported production for 1911 far exceeds that of 1910.

The coal production of the past year is slightly in excess of that reported for 1910. The total known acreage has been increased, as a result of recent studies made by the U. S. Geological Survey. It is estimated that there are in Wyoming 14,500,000 acres of coal land, valued at about \$670,000,000.

Joplin Lead and Zinc Production

The aggregate valuation of zinc and lead ores shipped from the Joplin district for 1911 was \$13,055,511, more than \$1,000,000 less than the total production for the previous year, and more than \$2,000,000 less than the record production of 1907. Taken by themselves, however, the shipments of lead were the heaviest in the history of

the district, due largely to the enormous production from the Webb City, Joplin, and Galena camps.

The new year dawns much more auspiciously in the mining district than did 1911. Prices for all ores are considerably better. Spelter is quoted \$1 higher than at the opening of 1911, and the demand for both metals and ores is extraordinarily heavy for this time of the year.

The accompanying table shows the yearly output, in districts, with their valuations of zinc and lead ores:

Camp.	Blende.		Calamine.		Lead.		Total value.
	Pounds.	Value.	Pounds.	Value.	Pounds.	Value.	
Webb City-Carterville, Mo.	189,376,352	\$3,828,906	49,239,545	\$1,428,076	\$5,256,982

Russian Mining in 1911

The two fine harvests of the years 1909 and 1910 had the inevitable result of making a fine business year of 1911, which has been characterized by remarkable activity in the mining and manufacturing industries of the country, and the total foreign trade of which bids fair to eclipse easily that of any preceding year. It is hard to say in which of the departments of mining the country has made most manifest progress in the year 1911; since in iron, coal, and copper the production has been a long way ahead of that of preceding years. That much is known already, but returns must be waited for from the goldfields before as much can be said of the industry of mining the precious metals.

In the South Russian coalfields, the Donetz basin, the output of coal has been remarkably large. And that this is not accounted for entirely by the high prices of liquid fuel driving the consumers back to coal, is shown by the fact that the production of coke has also been largely in excess of that of 1910, and the evidence that this has been called for by the iron works is to be seen in the fact that the production of cast, half-finished, and finished iron shows the best figures that these fields have been able to present. The real production of iron ore seems difficult to establish in more countries than Russia. The statistics, if gathered at all, do not appear to be considered worth publishing, and one is compelled to estimate the quantity of ore extracted by the quantity of iron smelted therefrom. Taking that as a basis, and even allowing for the fact that considerable reserves remaining over from 1910 were used by the furnaces, there appears to be no room for doubt that the iron mines have been exceptionally busy in 1911. It may be worth noting that the pig-iron famine was not entirely due to the short production consequent on the workmen fleeing the works because of the cholera, but also to the extraordinary demand that the various Russian manufacturing industries have made on the national metallurgical works for machinery. Among these—not least—was the great national sugar industry. But while the heavy metallurgical industry of the South has flourished, that of the classical Urals has sadly wasted, and even the coalfields of that area, by a reduced production, bear testimony to the fact that the better organized South leaves the local producers no chance in the competition; although the distance over which the southern products have to be carried is anything from 500 miles to 1000 or 1500, according to the district to be served.

Copper mining has been carried on vigorously through 1911 and the statistics show a distinct advance on the production of 1910, with an additional note that is more metallurgical than mining in point of interest. The production of electrolytic copper is becoming of greater importance in the country year by year. As is well known, the leading copper-producing centres are the Urals, the Caucasus, and Siberia, and in each of these substantial progress was made, and the hope continues to be expressed that the day is not far distant when Russia will smelt all the copper needed locally. That is an annually expressed pious wish, which up till now has not found fulfilment, not so much because her production has not kept up to her previous requirements, but because her requirements grow along with her production. With a rapidly reproducing population such as Russia's, now exceeding 150,000,000, and the increased energy displayed in her manufacturing industries, the demand for metals naturally grows, and the development in their production must increase at a greater ratio than at present if she is going to be a self-supporting copper country. It may be that one day the Caucasus will export copper, but it will probably be to the northwest provinces of Russia. This is a subject that has been dwelt on at considerable length in previous articles on Russian copper. Nothing particularly new is to be stated with respect to the equipment of the mines. Most of the increases are due to the initiative,

enterprise, and vigor of foreign proprietors, and it can be comfortably assumed without fear of error that these proprietors have introduced into the mines the most up-to-date machinery and plant. The cases where this is so could easily be specified; but there is no room to do other than make the statement.

Statistics must be awaited before passing an opinion on the gold industry. Naturally, in some districts where the foreigner is prominent, progress is to be reported. In others there certainly have been set-backs, due, as is always complained, to 'want of capital, want of technical knowledge, and want of energy all through,' defects which are repeatedly attributed by Russian critics to her countrymen when they are reviewing the national metallurgical industries. One of the features of the year has been the encouragement afforded by the building of the Amur railway. It continues to develop or reveal new gold veins; but the exploitation there, as elsewhere in the East, continues to suffer from the lack of labor, which is really an artificial want. For there is abundance of Chinese and Korean labor available if the Russian Government will let these people work. This it will not permit. Perhaps the most interesting feature in the gold industry is the continued increase in the use of machinery, particularly dredges, which for working placers in Siberia (and from these practically all the gold of the country comes) are coming more and more into favor. But here again the Government steps in and largely strangles the industry by allowing the Russian makers to make poor dredges at high prices by means of a high protective tariff, rather than allow efficient dredges to be imported from abroad, say from America or England. The gold producers complain continually, they telegraph to the Government, they petition the Government, but hitherto they have met with no satisfactory reply.

The allied industry is platinum. This has been a very active year for platinum; but high prices obtained have stimulated both large and small producers to do their best to make hay while the sun shines. Further, the cold weather has been late in coming, and consequently the small operators especially have been able to work for a much longer period than usual. It will have been a splendid platinum year. As for the associated metals, iridium, osmium, etc., the production of these is so infinitesimal as only to have a curious significance. They are eagerly inquired for, but are slow in coming forward. It will be some time before the statistics show what quantities of these have been locally separated from the platinum; though probably, as before, most of them have gone to foreign countries with the 83% platinum ore on which standard the official quotations are made.

Zinc and lead are produced in the country, the former in Poland particularly; but away in the Far East, zinc mines have been opened at Tetuch and exploitation is progressing at a great rate. Already there is a large export movement in zinc ore. Manganese has little to say for itself. It has been considered a ruined industry for a long time, and it is not believed that it can recover until the operators are able to produce ferro-manganese on the spot. The last reports from the manganese fields (Seharopan) were very despondent in tone. Various reasons are assigned for the decline, but the most probable one is foreign competition, because all the other reasons existed previous to the appearance of India and Brazil as rivals in manganese production.

Although the number of metals exploited in Russia is small, this is no index to the natural riches of the country. Many of the metals most prized in the world are plentiful enough here, and they will no doubt be exploited as occasion offers.

The most depressing feature of the Russian mining industry this year is in petroleum. The Baku wells, as their returns come in month by month, give every evidence that the forecasts of the previous few years have been correct. They are giving out, and there is little else in Russia that can afford any hope of taking their place. All the land called petroliferous in the Baku area

has not yet been let out; but there is not much to give away and when it is let competent authorities are of the opinion that, even if it has not been already seriously drained by the wells existing, it can never supply enough to bring back Baku to the grand producing days of 1904. Grozny continues to increase its production, but not at the same rate as formerly. Some enthusiasts think it will do as well as Baku one day, but there are not many of that opinion. Maikop, the petroleum field that was to dwarf Baku, and to become a serious menace to the Standard Oil Co. and the Dutch Royal in their struggle for the world's markets, has up to the present time proved to be a great disappointment. The wonderful wells of a year or two ago have become in some cases exhausted and in others are producing less than before. Boring, however, proceeds vigorously in the more hopeful parts of the field. The other oilfields of the country such as Uchta, which is in the prospecting stage still, and the Urals, a little north of Astrachan, which continues to produce a nominal quantity of oil, cannot be taken into account for the moment. It may be said of Uchta that the same authorities—and they are the giants of the Russian petroleum world—that spoke slightly of Maikop will simply have nothing to do with Uchta at all. Maikop appears to justify their views. Perhaps Uchta will surprise them. But it is in the north, and even if it furnishes a lot of oil, it will only be of local significance. One result of the scarcity of petroleum in Russia has been the great advance in the price, which naturally has materially reduced, if it has not more than made up for, the loss due to smaller production. Thus it may be said that while the more solid mining industries are doing well, the capricious oil industry is at last obviously yielding to the process of exhaustion.

The East Rand Fiasco

The official report of the Government Commission appointed to inquire into the East Rand Proprietary Mines affair, confirms all the statements made in the October 21 issue of the *Mining and Scientific Press* and goes further into details, showing into what straits the general manager has been driven in the attempts made to maintain the output and profits, as likewise to make it appear that the working costs were being lowered. It shows plainly that all the troubles at the East Rand Proprietary Mines were due primarily to overestimating the tonnage sent to the mill, perhaps with the object of apparently lowering the working costs per ton, but such a policy only led to more gold being reckoned on than was actually put through the works. To recover this missing gold the monthly clean-ups were increased in intensity, and when that failed to procure the desired output, the date of clean-up was gradually postponed until it reached the thirteenth day of the following month, instead of the first. Once started, this maneuvering did not end here. Mere estimates of the monthly outputs were supplied to the Chamber of Mines due on the 10th, while accidents and mishaps were made occasions when large tonnages of ore were put through the mill and not accounted for, in the hope of supplying some of the gold based on former estimates which had failed to materialize. Other acts of subtlety are disclosed in the report, made with the apparent object of lowering the costs and keeping up the profits, and the wonder is, perhaps, that the artful contrivances used did not in the least seem to ameliorate the position. Eventually, the general manager made a clean breast of the fact that the gold already declared had caused 13,000 oz. to be apparently missing; that to estimate future profits was impossible, while working costs thereafter must advance, and the available tonnage for the mill must in the future diminish. To the credit of the directors he it stated, that as soon as the actual position was officially disclosed to them, drastic and immediate steps were taken to put the matter right, but the mischief had been already done, for which, rightly or wrongly, several of the directors have been blamed, with the result that, at the time of writing, a

director who was not specially blamed felt it his duty to set an example by resigning from his position on the board. A further inquiry is to be made by the company into the whole administration of its affairs, and doubtless some radical changes will be necessary before the lost confidence is restored. One interesting query likely to result from the recent Government inquiry is whether the returns supplied to the Mines Department monthly did actually disclose the gold recovered each month, or were mere estimates when the monthly clean-ups were postponed to the 13th of the following month. The mining regulations provide that these monthly returns to the Mines Department shall disclose the actual output, and the forms are so elaborate and detailed that an estimate seems impossible and would probably be sure to fall short of the law's requirements. The Government has the power, moreover, to have these returns sworn to, should it be deemed necessary to do so. As in many respects the mining regulations in the Transvaal are more or less a dead letter, no surprise need be expressed even in this instance if a breach of the regulations is shown to have been committed, and the Mines Department may hesitate to institute a prosecution.

Copper Producers' Association Figures

The statement of the Copper Producers' Association for December shows a decrease in stocks on hand of 22,330,493 lb., as compared with the previous month. The production for December was 122,986,697 lb., as against 111,876,601 in November. Domestic consumption was 65,988,474 and exports 79,238,716 lb., compared with 68,039,776 and 67,049,279, respectively, in November. In the last month of the calendar year the stocks of metal on hand decreased 51,140,161 lb. This was more than an offset to the first five months, when increased stock ranged from 20,409,295 lb. in January to 44,000 in May.

Below are given the amounts, in pounds, of copper known to be available at the first of each of the last six months and for January of 1911:

	U. S.	Foreign.	World.
January	122,030,195	187,705,280	309,735,475
July	157,434,164	157,184,280	314,618,444
August	137,738,858	152,376,000	290,114,858
September	133,441,501	149,887,360	283,328,861
October	140,894,856	150,841,600	291,736,456
November	131,997,642	138,512,640	273,510,282
December	111,785,188	131,447,680	243,232,868

Nevada Dividends

During the year 1911 the mining companies of Nevada paid over \$12,000,000 in dividends, distributed as follows:

Goldfield Consolidated	\$ 7,118,296
Nevada Consolidated	1,800,000
Tonopah Mining Co.	1,650,000
Tonopah Belmont Co.	1,350,000
National Mines Co.	225,000
Florence Goldfield Co.	105,000
Junho Extension Co.	97,165
Montana Tonopah Co.	60,000
Manhattan Big Four Co.	32,196
Mexican Mining Co.	20,160
Ophir Mining Co.	20,160

Total dividends for 1911.....\$12,478,277

Dividends have been declared and will be paid in January, by the Goldfield Con. of \$1,779,574; by the Tonopah Mining Co., \$400,000; and by the Tonopah Belmont Co., \$375,000, making a total for the month of \$2,554,574. An estimate compiled by the correspondent of the *Mining and Scientific Press* of the gold production of Nevada in 1911 before the announcement of the preliminary estimate of the Director of the Mint, places the total at \$19,010,799, or within one fifth of 1% of the Mint figures.

Dark Scale of Hardness

By ALFRED C. LANE

*The hardness of a mineral is its resistance to shearing stress. Like other properties of minerals, it may differ in different directions. When two similar surfaces are rubbed together, the softer mineral leaves a powder 'streak' on the other. In order to be sure which mineral gives the streak, it is at times convenient to have besides the common Mohs scale of hardness, composed of light minerals, a 'dark scale of hardness' of minerals whose color and streak is dark, especially in teaching. For such minerals, the following properties are desirable: those of being quickly recognizable, easily obtainable, and uniform hardness. I have used the following minerals: (1) Graphite, with one good cleavage, at one extreme in the white scale, at the other extreme in the black. (2) Stibnite (Sb_2S_3), with two good cleavages, bladed. (3) Galenite (PbS_2), with three good cleavages. (4) Iron (use soft wire nail), magnetic, ductile. (5) Niccolite (NiAs), characteristic color, no cleavage. (6) Magnetite (Fe_3O_4), magnetic, brittle.

Cobalt and Its Market

Another interesting problem in connection with the cobalt-silver ores, is what to do with the cobalt. The situation is described in the report of the Bureau of Mines of Ontario for 1910, as follows: "The cobaltic oxide trade is at present demoralized, and is likely to remain in this condition until a greatly increased use of the article enables the demand to overtake the supply. The enforced production of cobalt ore from the mines at Cobalt has resulted in a much greater quantity of ore than can be converted into oxide and marketed as such. In fact, one year's operation of the Cobalt mines will produce ore enough to meet the present consumption of oxide for several years. The inevitable consequence has been a very decided fall in the price of cobaltic oxide. * * * Cobalt ore cannot at present be sold, and none is being hoisted from any of the silver-free veins of the Cobalt camp, the entire production being of ore associated with silver. * * * The only hope of absorbing the cobalt contents of the ores which will continue to be produced in Ontario is an enlarged demand, brought about either by the low levels to which the prices have fallen, or by new uses for the product. It is not unreasonable to expect that the former will lead to the latter."

Russian Gold Property Auctions

The annual auctions of gold-mining properties will be held in 1912, in the month of February, in the towns of Ekaterinburg and Tomsk, for the Urals and Tomsk mining Governments, respectively. The number of mines that will be put up for sale in the Urals district will be 525, and those in the Tomsk district will number 485. These auctions will include a number of mines already auctioned on which the deposits have been paid and forfeited. Many of them have already been worked; some of them not at all. The date of the auctions in Ekaterinburg is February 10 to 23, and in Tomsk, February 8 to 21, 1912. These auctions are supposed to indicate to some extent the condition of the gold industry in the regions where they are held. Some years ago after the Russo-Japanese war, it will be remembered, there was what was called the gold fever in respect to Siberian and Urals mines, respecting which the English particularly were affected, and gold-mining properties were bought up by Russians for a few shillings and offered to the greedy Englishmen at fabulous prices. This fever, however, has gone down, and the difficulty is to get those who have bid for the mines to hold on to their bargains. At the moment it can be said that there is no sign of a recurrence of the activity referred to; but one never knows what is going to happen.

*Presented at the Washington meeting, 1911, of the Geological Society of America.

Manganese Dioxide

Manganese dioxide has been known from very early times. In 1740 I. H. Pott showed that it did not contain iron, and that it yielded a definite series of salts, while in 1774 C. Scheele proved that it was the oxide of a distinctive material. The material was isolated by I. G. Gabu, in 1774, and in 1807 I. F. John obtained an impure material by reducing the carbonate at a high temperature with charcoal mixed with a small quantity of oil. R. Bunsen prepared the material by electrolyzing manganese chloride in a porous cell, surrounded by a carbon crucible containing hydrochloric acid. C. Brunner reduced the fluoride by metallic sodium, and E. Glabzel the chloride by magnesium. W. Moissan reduced the oxide with carbon in the electric furnace, and W. Goldschmidt has prepared the metal from the oxide by means of his Thermit process. W. H. Green and W. H. Wahl prepare a 97% manganese from pyrolusite by heating it with 30% sulphuric acid, the product being then converted into manganese oxide by heating in a current of reducing gas at a dull red heat, cooling in a reducing atmosphere, and finally reduced by heating with granulated aluminum in a magnesia crucible, with lime and fluorspar as a flux. A purer metal is obtained by reducing manganese amalgam by hydrogen. Prelinger's manganese has a specific gravity of 7.42, and the variety obtained by distilling pure manganese amalgam in vacuo is pyrophoric, and burns when heated in a current of sulphur dioxide. The pure metal gradually evolves hydrogen when acted upon by sulphuric and hydrochloric acids, and is readily attacked by dilute nitric acid. It precipitates many metals from solutions of their salts.

Oilfields of Mexico

Oil development in what is referred to as the Tampico territory in Mexico has been growing rapidly. Late in December 1910 the Pearson interests brought in at Potrero, in the State of Veracruz, the greatest oil gusher in the history of the oil industry, with the possible exception of the burned-out Dos Bocas, another Pearson well. Before it was brought under control the flow of the well reached 170,000 bbl. per day. Two pipe-lines have been built to give the gusher connection with the Tamiahua lagoon, and a third will carry oil to the port of Tuxpan. The Huasteca Petroleum Co. (Doheny) has had great success in the Juan Casiano field, and has established a second tank-farm that gives it a total storage capacity of about 10,000,000 bbl. of oil. The Huasteca will soon have a second pipeline from the Juan Casiano field to Tampico. The East Coast Oil Co., a Southern Pacific concern, has brought in two gushers in the Topila field. The Texas Oil Co. has bought land on the Panuco river for storage facilities, and will build pipe-lines to the Topila and other producing fields. The year 1911 saw the first shipments of Mexican oil to the United States. During the year several American and English companies have started exploration and development, and recently leases on several thousand acres have been taken for John Hays Hammond and Thomas J. Ryan. Rumors of pending transfers of the Pearson holdings to American interests have been current during the year, but so far as known no deal has been closed. A bill recently introduced in the Mexican Congress seeks to place oil lands on the same basis as mineral lands, and open them to denouncement. It is authoritatively stated that the projected National Railways line from Tampico to Veracruz, traversing the oil belt of the State of Veracruz, will be built.

L. VOGELSTEIN & Co. give the following figures of German consumption of foreign copper for the months January to October, 1911: Imports of copper, 157,934 tons; exports of copper, 7507 tons; consumption of copper, 150,427 tons; as compared with consumption during the same period in 1910 of 141,472 tons. Of this quantity 138,991 tons was imported from the United States.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Mass Copper

The Editor:

Sir—In your issue of December 2, in a short article on mass copper, you state that when large masses are found in the Lake Superior mines, high explosives are of little use in reducing the masses to fragments of a movable size, and the work required in cutting up such masses with a chisel is so expensive as to consume the larger part of the profit from their extraction.

In the very old days of fifty to sixty years ago, when black powder was the only explosive, and masses of native copper of enormous size were found occasionally running up into the hundreds of tons, the work of extracting the masses by means of long-handled chisels was very slow and costly. Gradually this work was reduced to a better business basis; but any sort of an explosive is but poorly adapted to breaking mass copper, though it will break the mass out from the surrounding rock. For the past ten years or so, pneumatic chisels have been employed to excellent advantage, in cutting up heavy mass copper found underground. With the powerful hoists and large skips now in use, it is possible to hoist masses up to ten tons in weight, and these are, if necessary, hand-cobbed, or perhaps cobbed under a steam-hammer in the rock-house, and then transported to the smelters, where they are dropped into the reverberatories by taking off the tops. Pneumatic chisels give about four times the efficiency of the old plan of hand-chiseling, and masses are divided by simply cutting channels, from which are taken ribbons of metal five-eighths of an inch in width, and averaging perhaps a quarter inch in thickness.

HORACE J. STEVENS.

Houghton, Michigan, December 27, 1911.

Stamp-Battery Cam-Shafts

The Editor:

Sir—In your issue of December 16, C. T. Hutchinson gives some interesting details of stamp-mill construction. During the last twenty years of experience with stamp-mills I have been in but one mill where a cam-shaft had broken, and, as it happened, that shaft was not on the side of the mill of which I had charge. Of course, I have seen cam-shafts that had broken, and many of them. The chief cause I believe to be due to the boxes getting out of alignment, and one would expect the more boxes the greater the chance of a broken shaft. Now, it has been my fortune to have never seen or heard of a five-stamp unit cam-shaft breaking. Then why not adopt the unit of five stamps instead of the ten, fifteen, and twenty-stamp unit? I know the fifteen and twenty-stamp units are obsolete, but the ten-stamp unit is the standard for all large mills. The unit of five stamps is objected to on account of the movements on the end opposite the bull-wheel. If the battery has been well put together with concrete foundations and the battery posts made of concrete, or the wooden battery posts well anchored to the concrete sole-plate, the vibrations are little more, and in many cases not as great as those in the ten-unit cam-shaft. It is not even necessary to cap the outer box.

Mr. Hutchinson says that the question of "keeping the cam-shaft bearings in line will never be satisfactorily settled until the concrete, reinforced, self-contained battery-frame construction is employed, and installed without being connected in any way with the ore-bin." Two years ago I suggested certain departures from the regular type of construction, though the matter was not then published.

The principal departure was in placing the line-shaft immediately under the cam-shaft, so that the pull would be vertical, and therefore the tendency of the frame to move toward or away from the ore-bin would be negative. I had arrived at this notion as an improvement on the all-concrete battery-post construction that I had proposed in the *Engineering and Mining Journal* some years ago, because I saw that the self-contained concrete structure must have a vertical pull so as to reduce the tendency to tip backward or forward, which would be present if the pull was from the ore-bin side of the centre where the line-shaft is usually placed. That concrete structure should have guide girts, made of cast iron, attached to the concrete.

This idea has since been put to practical test in the City Deep mill, as Mr. Hutchinson states; but to lessen the vibrations of the cam-shaft I proposed a bearing between each stamp. This, then, gave thirteen bearings for every ten stamps, but as these were all to be on a heavy casting the bearings could not get out of alignment, although the shaft might get out of the horizontal if the concrete work should settle or the timbers on which this casting rested should contract unevenly—two conditions that are not likely to occur. Another radical departure was that of a low mortar box, with the boss projecting through the top, a feature by no means original with me, as M. P. Boss had long before adopted it. The battery plates also were placed away from the mortar, and in its place a car provided running alongside to carry shoes, dies, etc., to the mortar, and battery sands away to the clean-up barrel, or worn-out pieces to the scrap heap. I have heard millmen object to this, because, as they contend, the pulp cannot be distributed as well away from the battery as when issuing from the screen. This, in my opinion, requires simply a little ingenuity in making a distributor. I would also have the back knee supports held in shoes that allow of the lengthening or shortening of the braces—an adjustment that would require in practice but a few moments time.

Mr. Hutchinson says that chrome-nickel steel is the best material for cam-shafts; yet, if I am not mistaken, this material was used in the Boston Con. mill and broke so frequently that a change was made to malleable iron, since which time no trouble has been experienced. The vibrations of a cam-shaft in a stamp-mill are not exactly those in the axle of an automobile, and so while chrome-nickel steel may be good for one purpose, it may be of little use in the other, where the vibrations are of a different character. As Mr. Hutchinson says, nothing but price is considered in placing orders for machinery. It may be that the mine-owner consults an engineer who obtains the price with specifications from many machinery houses, but how often does the engineer have the ultimate choice? Machinery houses should insist upon minimum sizes for certain parts of mills; the quality of the material must be left to a competitive price. A six-inch cam-shaft, while not strong enough for a ten-stamp unit, is plenty large enough for a five-stamp battery. Some houses offer a 5½-in. shaft for a five-stamp battery, but this is not strong enough. This size is well suited for a two-stamp unit.

I would suggest the 'mortar hold down bolts' two inches in diameter. This I consider the correct size for concrete foundations. Only six of these are needed, three on each side, and, as some millwright has suggested, four good bolts will answer the purpose as well as eight. The battery posts should be held down to the sole-plate with 1½-in. bolts and not the usual inch bolts. The sole-plate may be held down by removable bolts, as used for the mortar construction; but, as Mr. Hutchinson indicates, the all-concrete, reinforced battery construction will no doubt come into vogue as soon as the mining man throws off some of his conservatism and looks upon his mine as a commercial business instead of a stock-jobbing enterprise.

ALGERNON DEL MAR.

South Pasadena, December 20, 1911.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

PATENTS can now be registered and kept alive in Japan as in any other country. The original fee is about \$25, and renewal costs \$10 per year. In case a patentee does not within a certain time register his patent, anyone else caring to do so may register it in his own name and collect royalties.

FILES clogged with tin or lead may be cleaned by immersion in strong nitric acid. For iron filings, use blue vitriol, rinse in water, and dip in nitric acid. For copper or brass, use nitric acid several times; for zinc, dilute sulphuric acid. After any of these treatments, rinse the files in water, brush vigorously, and dry in sawdust or by burning alcohol on the file.

TIN occurs in America chiefly in the Black Hills of South Dakota, at Spearfish, and at Harney Peak. Litigation has hampered the development of the properties, which are not of high grade, and the operations have not been successful. Tin is chiefly obtained from the Straits Settlements, though Bolivia, Cornwall, and China are important producers as well.

GARNET is used as an abrasive, the variety known as almandine being preferred for this purpose. The present production is obtained from the Adirondack mountains, in New York, where the crushed rock is either hand-sorted or jigged. It is made into garnet paper, which is used in the shoe and wood-working industries, and brings \$30 to \$32 per ton.

THE following is a short accurate method for securing length for a belt. When it is not convenient or possible to measure with line the required amount of belt needed, add the diameter of the two pulleys together, divide the result by 2, and multiply the quotient by $3\frac{1}{8}$. Add your product to twice the distance between the shafts carrying the pulleys and the result is the length for belt.

SISKIYOU, a county in California, and mountains in Oregon, by some authorities is said to be a corruption of the original name given the district in California by the French—*six cailloux*, meaning 'six boulders'; others state that it is an Indian word meaning 'bob-tailed horse,' the mountains between California and Oregon having been so named because a famous bob-tailed race-horse was lost on the trail.

MONAZITE SAND from the interior of Brazil contains only 4 to 5.7% of thorium oxide, while that from the sea coast contains 7%. The deposits have resulted from the erosion and concentration of feldspathic rocks which contain 0.07 to 0.20% of thorium. The sand is mined and concentrated roughly and is finished on electromagnetic separators which make a 95% monazite that contains 3.7% thorium oxide on the average.

GROUND which is the subject of an adverse claim may be excluded from the patent application, that the latter may at once proceed to final entry and patent, without any rights to the ground in conflict being waived. An agreement made by a patent applicant to deed certain portions of the claims or rights, after patent has been obtained, to those threatening to adverse, in consideration of no adverse being made, is sound and valid.

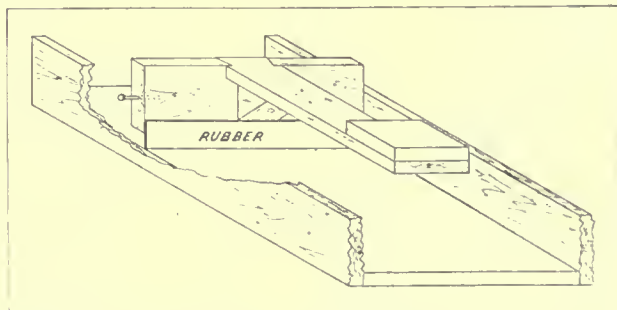

LOSS OF GOLD in amalgamation may be due to a number of causes. If it be due to free gold included in or surrounded by gangue rock, a sizing test will reveal it through the higher value of the coarser sand. In some cases the coarser sand can be crushed in a mortar and

panned to show a 'prospect' of gold. The remedy for the loss is to crush fine, not the ore in general, but the coarser grains. This may be accomplished by using a finer screen with the same or lower height of discharge.

ELECTROLYTIC refining of copper, as is true of all other processes, involves some waste and re-treatment of material. The large loss is due to a part of the anode, used for supporting the weight, becoming scrap. In Eastern refineries it is customary to use anodes where a lip projects from either end of the upper edge, and the material in these lips is necessarily left unrefined and must be remelted. Scrap in this process amounts to as much as 12%. At Great Falls the scrap has been reduced to 7% by means of an ingenious device perfected by the superintendent, Willis T. Burns. Briefly, the weight of the anode is supported by two loops of copper wire in place of the usual lips. The ends of these loops are placed in the molds when the anodes are cast, and thus the copper in the wire loop becomes firmly imbedded in the copper of the anode. At the end of the refining process the amount of copper left to be re-treated is much less than when the usual form of anode is used.

ISOPLANATION, as a term complimentary to peneplanation, was defined at the recent meeting of the Geological Society of America by D. D. Cairnes, on the basis of physiographic studies made by him in the Yukon region. "Where remnants of the original plateau surface remain," he said, "agencies, including nivation, frost, and chemical action, are at work on the upland tending to remove all inequalities of the surface by transporting material from the upper to the adjoining lower levels; for this process the term 'isoplanation' is proposed. This name has suggested itself, as its results tend to make the elevation of all points equal (iso) in the area affected. Isoplanation is the reverse of peneplanation, as by isoplanation there is but a slight, if any, loss of material within the planated areas, but in peneplanated tracts all crustal matter above sea-level tends to become transported to the ocean. Isoplanation thus includes all planating activities, even wind action, whereby a plain-like surface tends to be produced, and by which there is no perceptible loss of material to the planated tract: all ordinary stream action, which is the main factor in peneplanation, is thus excluded."

SCREENING fine material over fixed screens where feasible, is less expensive than where trommels are used, because of power and repair bills incident to the latter. Where feed is irregular, however, there is a marked tendency for material to slide over the screen in a mass, and so to be delivered imperfectly screened. At the Portland mill at Colorado Springs this difficulty has been met by means of the device shown below. Across the screen is

placed a tipping block swung on pins and weighted by means of an arm as shown. Along the lower edge of this block is fixed a strip of rubber belting, fitting down close to the screen. When a mass of material is dumped on the screen it slides down against the rubber strip and bounces the block up and out of the way. The counterweight throws the block back into position and the material is, as a result, spread evenly over the screen by a series of light blows. This greatly increases the efficiency of the screen.

Special Correspondence

SALT LAKE CITY, UTAH

NEWS FROM COTTONWOOD CANYON.—MICHIGAN-UTAH.—
ALTA T. & T. Co.—ALTA CONSOLIDATED.

The Michigan-Utah Mining Co. has been organized to take over a number of important mining properties lying on and between Big and Little Cottonwood canyons, in Salt Lake county, on a basis tentatively agreed upon in arranging for a big consolidation. The properties proposed to be merged consist of the Utah Mines Coalition, City Rocks, Grizzly, Copper, Prince, International, Kearsarge, Gen. Monk, and Gen. May. The Utah Mines Coalition and City Rocks are developed to the productive stage, and all form a contiguous group. The property of the Coalition company has been operated some time through its Solitude tunnel, which can be utilized in working the City Rocks. It is demonstrated that, by driving a 600-ft. cross-cut from this tunnel, a connection may be made with the Grizzly workings; and by other driving this haulage level can be made to serve all other properties of the group. The man-

MAP OF UTAH.

ager and officers of the Utah Mines Coalition Co. took the initiative in securing the agreement by which all these properties are in a fair way to be united under the control of the Michigan-Utah M. Co. These properties are in the Alta district.

The Alta Tunnel & Transportation Co., in which F. V. Bodfish, C. A. Gillette, John Caine, George H. Rathman, and R. L. Mack are directors, has acquired 14 lode claims on Honeycomb mountain between Big and Little Cottonwood canyons. The plan of the company is to cross-cut the fissures of this region by driving an adit 3500 ft. from Silver fork on Big Cottonwood. The portal will be at an altitude of 8500 ft. above sea-level, and it is figured that the adit will cut several well-known fissures at depths ranging from 600 to 900 ft. below existing workings. It is the purpose to place an air-compressor at the entrance, and this will be electrically driven. The cross-section is to be 5 by 7½ ft., and the estimated cost of driving is \$15 per foot. It is stated that this adit will give a depth of about 600 ft. below the Solitude haulage level of the Utah Mines Coalition Co. The fissures to be intersected are nearly parallel. They occur in a formation of shale, quartzite, and limestone, overlying granite. The fissure veins strike parallel to a series of porphyry dikes which extend north-

easterly through this formation. The shoots of ore in the veins pitch toward the northeast. The dip of the veins is northwest, about 80° from the horizontal. The ores mined thus far are mostly oxidized, the metals being silver, lead, and copper, with a small amount of gold. The lead and copper in the higher workings occur as carbonates, the silver as chloride and bromide. The proposed deeper development is expected to open the bodies of sulphide ore. Former operators in this vicinity mined through shafts and were handicapped by the excessive inflow of water at their lower workings. The projected adit is to serve for both drainage and transportation, and will make it possible to mine ore in this and adjoining properties without hoisting. The course is in the direction of Alta camp, which is in Little Cottonwood canyon.

The Alta Consolidated M. Co., having a lease and bond on a group of developed claims almost at the head of Little Cottonwood canyon, has shipped over 300 tons of ore within the last five months, the gross returns of which amounted to \$12,000. The ore sampled about 18% galena, 5% copper, and 75 oz. silver per ton. Originally the work here was in carbonate ore, but present operations are entirely in sulphide bodies. The lowest level is being advanced on the fissure vein in the direction of a contact which cuts the fissure nearly at right angles; according to past experience in this district, larger bodies of ore may be found at this contact. The property is at an altitude of 9500 ft., and adjoins the Michigan-Utah group. J. H. Winwood, T. and A. Jacobson, and Hans Vunder are in control of the property.

JOPLIN, MISSOURI

ZINC PROSPECTS FOR 1912 BRIGHT.—NEW CONTRACTS.—
ZINC OXIDE WORKS MAY RESUME OPERATIONS.—ZINC
AND LEAD NOTES.

The dawn of 1912 sees conditions exceptionally bright in the zinc industry, both mining and smelting, and the ore production from the Missouri-Kansas-Oklahoma district is much heavier than at the beginning of 1911. Spelter, which reached the highest figure of years by going to \$6.85 early in December, dropped to \$6.10 toward the middle of the month, but recovered, and at the close of the year was firm at \$6.20; while zincblende, which had been selling for about \$48, assay basis of 60% metallic zinc, earlier in the month, dropped to \$44 at the close of the month, with choice lots commanding a premium, bringing the price to as high as \$48. During the past year metal producers have reaped a profit much greater proportionately than have the mine operators, due to the wide margin that has existed between the price of spelter and the price of ore. At no time has the 'eight-to-one' basis prevailed. Formerly it was considered that zincblende should bring eight times as much, per ton, as spelter brought per hundredweight, but this ratio has been materially decreased. In 1910, when a \$12 smelting margin prevailed, profits were said to be good; but in 1911 the margin ranged around \$20, and actually went to \$28 toward the close of the year. Realizing that they have not been united in their fight for higher prices, the ore producers appreciate the fact that through coöperation only will they secure a price which they believe to be reasonable. Without coöperation the heavy production of blende continues unimpeded, more than 5000 tons per week being turned out, to be placed on the market at any figure the smelters care to offer. With unity of action, the zinc-ore producers can restrict this output, and can to some degree at least have a voice in fixing the price on their product.

A new scale of buying zinc ore has been put in force by the American Zinc, Lead & Smelting Co., which a year ago inaugurated for the first time in the history of this district a method by which the mine product should be bought at a price fixed on the average price of spelter at East St. Louis. The new contracts are much less favorable to the mine operator and are not being accepted as readily as were the former contracts. While the old con-

tract fixed a smelting margin of \$14.80, the new contract fixes a margin of \$21, and many features of the contract are much less desirable. It means that the producer will receive from \$6 to \$8 per ton less for his output than under the former schedule. The contract system was employed only by the one company and was largely in the nature of an experiment. The numerous other companies buying in this market purchased their ores in the old way, by bidding in the open market. Comparison of the two methods throughout 1911 shows the contract, as originally employed, to have been much more favorable to the producer than the open market bidding. Contract prices invariably were much higher than the open-market figures, the difference between the two at times being as great as \$5 per ton.

After remaining idle more than four years, operations are to be resumed at the plant of the Ozark Zinc Oxide Co. at Joplin, officers of the company having decided to spend \$10,000 on repairs. The plant will be ready for work about April and will employ about 35 skilled workmen. It will open a new market for some of the zinc ores of the Joplin district, though Mexican and Western ores are used almost exclusively.

Having worked for years on an enormous ore deposit that netted thousands of tons of high-grade blende and galena concentrate, the Grace Zinc Co.'s mill on the Granby M. & S. Co.'s land at Joplin is being converted into a tailing mill, the object being to rehandle the great bulk of lime and flint gravel that passed through the plant in the years of its operation.

ARCO, IDAHO

WILBERT M. CO. ERECTING 150-TON MILL.—PROPERTY DESCRIBED AND PLANS OUTLINED.

The Wilbert Mines Co. is erecting a concentrating mill of 150 tons daily capacity at its mining property situated in Little Lost river range, Dome district, 25 miles northeast of here. It is expected that the mill will be ready to operate by next March. This plant is being equipped with a 10 by 20-in. Blake crusher, two sets of 36 by 16-in. rolls of Allis-Chalmers make, four Harz jigs, eight Wilfley tables, two slimers, and a 5-compartment Janney classifier for classifying the product of the fine rolls. The middling and tailing from the coarse tables are to be re-ground in a Hardinge 6-ft. conical mill, the product of the latter to be concentrated over slime-tables. A 20-ft. picking belt will extend from the bin to the crusher. It is estimated that 15% of the ore to be taken from the mine is high-grade, and this class of ore is to be picked off the belt and shipped without concentrating. The ore consists of galena and silver in a quartzite gangue. M. M. Johnson, the company's consulting engineer, has made a report on the property in which he gives an estimate of 21,958 tons of ore exposed and ready for mining. Assays of about 200 samples of this ore show an average of 23% lead and 2 oz. silver per ton, with about 15c. gold, making a gross value of \$21.85 per ton. In this report it is figured that there will be a loss of 20%, or \$4.54, in milling, and that costs will be 75c. for mining, 75c. for milling, \$2 for wagon haulage, \$1.25 for railroad freight, \$5.80 as smelting charge, making a total of \$14.89 per ton, leaving a net value of \$6.96 per ton. It is calculated that the concentrate to be shipped will run 50% lead and 5 to 6 oz. silver per ton.

The holdings of the company consist of 15 lode claims, covering in the main a quartzite country, in which there are several well-defined fissures striking northeast. The mineralization, as indicated by the croppings, extends about 3000 ft. and has a width of 1000 ft. The principal development has been accomplished by means of No. 1, 2, and 3 cross-cut adits, the last-named giving a depth on the principal vein of about 200 ft. The orebody exposed by the development already performed has an average width of 21 ft., is 70 ft. long, and 180 ft. deep. What is believed to be the northerly extension of this orebody has been opened by a fourth adit known as the 'caved tunnel,'

150 ft. north of the former workings. The vein exposed by the caved tunnel is 10 ft. wide, the ore assaying 16% lead. There is at this place an extensive wash of surface ore. The ore reserve indicated has been blocked out and is susceptible to measurement. The mill is situated near the base of the mountain, 900 ft. from the portal of adit No. 3, and the ore is to be hauled to the mill-bins in cars over a surface tramway of that length. The intention is to drive a haulage level to the orebody from the level of the mill-bins, whereby an additional depth of 400 ft. will be gained. While a steam plant is being erected at the mill for temporary power purposes, the intention is to build a hydro-electric power-plant on one of the three creeks which flow through the company's ground, a grant for the water rights of which has been obtained from the State of Idaho. A. S. Ross, one of the principal owners of the Pittsburg-Idaho mine, at Gilmore, Lemhi county, Idaho, has a controlling interest in the Wilbert mine. W. S. McCormick, Knight & Warnock, and others, of Salt Lake, are also stockholders. The Wilbert and Pittsburg-Idaho are about 50 miles apart, and situated on opposite sides of the same mountain range, both being lead mines. The latter is connected with a spur from the Pittsburg & Gilmore railroad, which extends from Armsted to Salmon City, and is a regular shipper of ore.

JOHANNESBURG, TRANSVAAL

MINES DEPARTMENT TELLS OF MINERAL PRODUCTION.—
COAL.—TIN.

According to the returns issued by the Government Mines Department, the total value of the mineral output of the Transvaal, exclusive of diamonds, was, for October, £3,137,387. Considering that gold alone amounted to £3,006,438, the balance may not appear to be a large amount to distribute among the base-mineral output, but, nevertheless, base minerals have made some progress of late. Coal, of course, has always been a drug on the market since the country became possessed of a railway system, and selling prices have been constantly falling, until in October the average price at the pits was but 4s. 6d. per ton. The district commanding the highest average pit-top selling price had to be content with 5s. 7d. per ton, while the cheapest district only obtained 3s. 9d. per ton. It is clear that the last price does not leave much margin for profit, and is obtained under somewhat exceptional circumstances. Owing to the efforts of the Transvaal Coal Owners' Association, coal prices, though low, are steady, and the majority of collieries lately have been able to earn a small dividend for the shareholders.

The value of tin ore shipped during October was again somewhat disappointing, as it only amounted to £26,181, as compared with £45,009 in July. This fall seems probably due to the Zaaipplaats mine, the principal producer in the Transvaal, not having been so overpushed to obtain a maximum output and shipments since the manager has returned, for there are few producing mines as yet in the Waterburg district, and a marked restriction of output at any one brings down the monthly returns for the whole country. Affairs at the Zaaipplaats mine have not been running smoothly of late, as the manager has persistently refused to adopt the suggestions of the acting manager and consulting engineer, regarding the equipment and policy. The directors, after agreeing to the proposed method and acting upon it, have now withdrawn their consent to its adoption, upon the wishes and threats of the manager. It is believed that the plan of the consulting engineer was largely suggested by the acting manager, and no surprise need be expressed that affairs have recently been somewhat topsy turvy. The Zaaipplaats mine is a phenomenally rich one in places, and the doings there must have some effect upon the fortunes of the whole tin deposits in that district. Copper ore also was shipped during October to the amount of only £3014, although in August shipments had grown to £5907. When once the new railway is constructed to the northern copper fields, there is every indication that copper shipments will materially increase.

NEW YORK

DULL MARKETS CONTINUE.—WHERE IS THE COPPER?—PROMOTERS IN TROUBLE.—NEW SMELTERS DEFERRED.

January is the month of dividend distribution, and some \$225,000,000, it is estimated, will be disbursed. Last July, when the summer semi-annual distribution was made, market authorities declared that the resulting evidences of expenditure could be found along the automobile highways; that those who before had no cars were making their first payments and taking their first trips, that those who had previously had cars were investing their dividends in new tires and other accessories, to say nothing of the gallons and gallons of gasoline required. It was hoped that in the winter season it might be possible to draw the attention of the public from other things and create some speculative interest; it is something of a shock to the old-timers to find that the public is through speculating, whether the market goes up or down. Shares bought for investment do not greatly interest the makers of markets; they prefer the trader for market profits who goes in and out every day. The sorrow of Wall Street is that, like Western big game, good specimens are becoming more and more rare.

In copper there seems to be a good deal of underlying skepticism concerning the recent upward trend in prices. Some of the large consumers are questioning the soundness of the situation and the movement in the shares hardly justifies the fears expressed by some of the producers of a runaway market. While it is not known as an absolute certainty that a pool of big producers was formed during the latter months of last year, it is so asserted in some quarters, the story being that the group included some of the more important foreign agencies, and that a large amount of copper has been accumulated in an endeavor to stampede the American manufacturer into the market. Discussion of the topic with manufacturers reveals the fact that many of them were, and are, uneasy over the prospect of higher prices and no metal on hand, but, while the report of the Producers' Association for December 1911 was expected to make a strong showing, there was a tendency to await developments. If it be true that a group of copper producers working with the larger selling agencies has purchased and is now carrying any large part of the copper which is supposed to have gone into consumption, if the decrease in the world's visible supply proves eventually to be accounted for in this way, it is safe to say that in the end the copper market will suffer more than it will gain. In the meantime, one factor may be taken as assured—every producing mine that can take out copper at a satisfactory profit on the present market is straining to bring production up to capacity. An instance of the quick expansion in production which may be anticipated is the record of the Anaconda for December, which turned out 24,400,000 lb., being an increase of some 3,500,000 lb. over the figures for the month preceding, and considerably more than any month of the year. The Phelps-Dodge output has already shown a marked increase and may be expected to grow further. December output was 13,199,042 lb., as against an average of about 11,000,000 lb. for the preceding months of the year. If similar increases are to be made by the larger mines, February or March will probably see the surplus gaining in bulk once more. The foreign visible supply is shown by fortnightly figures to show an increase on December 31 of something over 1,500,000 lb. It is rather expected that December export figures will break all previous records.

The trial of George Graham Rice and his associates is still dragging along, without other incident than the action of the court in forfeiting the bail of the principal defendant. The spectacular methods of Albert Freeman and his association with Julian Hawthorne have been the subject of a great deal of comment during the past eighteen months, during which time, these two and their co-workers, among whom was Josiah Quincy, a former mayor of Boston, Massachusetts, floated several properties in Canada. The glittering prospectuses, written by Mr. Hawthorne and spread broadcast through the mails, are now declared to have

been instruments of fraud, and the six principals are held in heavy bail for misusing the mails.

Some of the projected smelting plants are evidently not to be built, at least in the immediate future. The Giroux company, which has had a long hard pull in its attempt to make a copper, is said to be making a contract with the Steptoe Valley S. & M. Co. for treatment of its ores. The Shattuck-Arizona is endeavoring to obtain a satisfactory smelting contract, and if possible to postpone the erection of its own plant. The governing factor in both cases undoubtedly is the intention to take advantage of the present metal market and avoid the delay necessary to construction. The Calumet & Arizona, however, is in better stead, having a plant which can be used while the new smelter, which is to cost about \$2,000,000, is being erected.

It has been a long time since the New York market took any particular active interest in Cripple Creek, but an effort is to be made to make a trading market in El Paso Consolidated on the New York Curb.

Business of the U. S. Steel Corporation continues to show improvement, and the volume of new orders is now greater than in months past. It is said that business now averages 55,000 tons per day. The Corporation has also increased its production, and operations are now at 80% of capacity. Because of the increase in business in December and the slightly higher range of prices, it is estimated that earnings for the quarter closed December 31 amounted to between \$24,000,000 and \$25,000,000.

BUTTE, MONTANA

ANACONDA AND BUTTE-BALLAKLAVA MAY SETTLE DISPUTE OUT OF COURT.—WORK STARTED ON BUTTE CENTRAL CONCENTRATOR.—ANACONDA PRODUCTION.

There are rumors afloat to the effect that a settlement of the litigation between the Anaconda Copper Mining Co. and the Butte-Ballaklava company might be made in the next few weeks. In the application for the hearing of the case in some other place outside of Butte, the Butte-Ballaklava company asserted that it was impossible to get a fair trial in this city owing to the powerful influence of the Anaconda company. W. H. Weed, of New York, who is the expert of the Butte-Ballaklava company, and H. V. Winchell, who acts for the Anaconda company, many months ago completed all their examinations, and are here. They have had some conferences, and while neither one of them will express any opinion, it is thought they are discussing a possible line of agreement for submission to the interested parties, both acting in behalf of the companies they represent. The contention of the Anaconda company is that the Butte-Ballaklava company was taking ore from the Right Bower and the Mountain Chief properties, and \$1,800,000 is asked as the value of the ore taken. The Butte-Ballaklava company prospered for some time previous to the Anaconda company, securing an injunction prohibiting it from mining in the ground in dispute, and even paid one dividend. Since the injunction has been in force, the Butte-Ballaklava company has sunk the shaft 200 ft. and has carried on some development work in ground other than the territory claimed by the Anaconda company, but with little success.

Work has been commenced on the concentrator of the Butte Central Copper Co., and it is announced the plant is to be ready for operation by June 1. It will have a capacity of 100 tons and will be operated by electricity. The company is maintaining shipments of about 50 tons per week from its Ophir mine, and Sam McConnell, superintendent of the property, says that more than sufficient money is being received from the shipments to pay all running expenses.

It would appear from the official figures of the production of the Anaconda company for the month of December that the output was increased 2,500,000 lb. during that month, and that it was 24,400,000 lb., or within 600,000 lb. of the amount announced to be increased this year. This was the largest output of any month last year and brings the production of the Anaconda for the year

1911 up to 260,652,000 lb., and adding the East Butte company makes the total production for the year in this district 273,238,000 lb. of copper. So, while the increase was started in December, it will be continued this month, when the production probably will slightly exceed 25,000,000 lb., as the High Ore, which was closed down since August 23 of last year, has gone into commission again and some of the other mines have slightly increased their output. The Leonard has been closed down, and it was hoisting 1200 tons per day, but the High Ore will more than make up for the closing down of the Leonard. The High Ore, during the time it was out of commission, in addition to being equipped for hoisting ore by compressed air, had skip chutes built at different stations into which the ore is dumped to be held in readiness to be hoisted to the surface. The skip chutes are of the most modern kind and will greatly facilitate the work of getting the rock to the surface in large quantities. The Badger State and Tramway mines, before the end of the month, will be hoisting increased quantities of ore, but not much over one-half what they could produce if the occasion required it. These mines are among the richest in the district and are in excellent condition.

Now that the Anaconda company has announced an increase in production, both the East Butte and Tuolumne companies will follow suit in the near future. The Tuolumne company's new surface plant will not be ready to go into commission much before the last of the month, and it will therefore be along about the first of next month before this mine shows any increase. The East Butte is not likely to increase its output much before the first of the month, although there is an immense quantity of ore blocked out and ready to be brought to the surface. The smelter capacity will be increased in the near future by the adding of a new blast-furnace, the installation of which is now under way.

TEPIC, MEXICO

OLD MINES REOPENING.—RAILWAY CONNECTION SOON.

El Frontal, which is east of the town of Rosamorada, Tepic, some six hours' horseback ride from the railroad line, and is owned by an American company having offices in Cincinnati, is now attracting attention. Extensive development work has been done during the past three years and a large tonnage of ore has been blocked. A body of ore 7 ft. wide, reported to assay \$11 per ton, was found last month in a cross-cut 250 ft. below the adit-level. The mill and cyanide plant which was erected two years ago, but not started for lack of sufficient tonnage, are being put in shape and will commence operations in February. A large tract of land, well wooded and watered, surrounds the property and was purchased by the company several years ago. The company also owns a promising prospect near the Southern Pacific railroad station Yago, called La Cucaracha. No prospect work has been done on this property, but surface assays of the outcrop, which is wide, show very good values in gold and silver. There are a number of old Spanish workings on this property. With the facilities which the new railroad affords, this property ought to offer many advantages for operation.

The Minitas, situated some five minutes' ride from the Southern Pacific railroad station Rosamorada, is steadily keeping up development. The flow of water which for some time greatly impeded the work, has been controlled by the aid of a powerful pumping plant. According to records, this property, which, judging by the many old workings scattered along the vein, must have been worked very extensively by the Spaniards during colonial times, was a large producer. The company's representative, E. J. Thomas of Ray, Arizona, was on the ground during the month of December and acquired some promising claims from L. J. Hall, whose claims are situated in the neighborhood of the town of Acaponeta, near the famous El Tigre mine which has been shipping high-grade gold ore to San Francisco for the past two years. Cucharas, situated in the municipality of Acaponeta, near the village of Huajicori, is owned by the Lacy family of Los Angeles and

managed by one of the three brothers, Ed. Lacy. This is a copper-gold mine and said to have large reserves of ore blocked. The Cucharas was one of the few, if not the only mine in the Territory, which shut down during the revolutionary trouble in May 1911. Work has been resumed in December, and the smelter will be started within a month.

The Zopilote property is owned by a German company with offices in Hamburg. It is one of the largest, if not the largest, mines in the Territory of Tepic. Before the German company acquired it in the eighties, the mines were owned by several Mexicans who worked them for years with large profits. Although no record of the production during those times exists, it is stated on good authority that several million pesos were taken out. The German company acquired all of the eleven mines now comprising the Zopilote group, and also a large tract of some 30,000 acres of land surrounding it, and erected a stamp-mill and hypo-lixiviation plant. There are a number of substantial administration buildings and a pleasant town of brick houses erected by the company and accommodating some 2000 people, a church, a schoolhouse, etc. The German company worked the property without interruption for about 25 years, milling during the last ten years about 500 tons per month. During this time the property has produced some \$10,000,000. The ore was roasted and treated by the hypo-lixiviation process, at a very high cost. In the year 1908 the property closed on account of the low price of silver. A. F. Flynt, a mining and metallurgical engineer of Minnesota, acquired the property under lease and option in May last, and, notwithstanding the revolutionary trouble in the country, he started work at once. The 20-stamp mill and the two ball-mills were repaired and put in commission, a concentrator was erected, and the old hypo-lixiviation plant was converted into a cyanide plant. Milling commenced in August. Since that time the plant has run without interruption, the property employing some 200 men. The shipments are from \$10,000 to \$15,000 per month. There are large reserves of low-grade ore in the mines, as the old company did not attempt to work any ore assaying less than one kilogram of silver per ton. The ores from the Jabalina and Restauradora mines are being worked at present. Some high-grade ore running from 6 to 10 kg. of silver per ton is reported to have been found in both these mines. There is a fine water-power near the property, which it is planned to develop. This property ought to become a large producer with a further increase in the capacity of the plant.

The Tenamache is situated on the edge of the ground belonging to the Zopilote company and is owned by an American company controlled by a Mr. Ramsdell of Guadalajara. Development has been under way for the past three years, opening up old Spanish workings. H. Hale, who did the development work at the Favor mines in the Hostotipaquillo district before Mr. Ramsdell sold them, is in charge. The ores are silver bearing, and the mine is said to contain high-grade ore. There is no mill on the property, but a shipment is now being made ready to be sent over the Southern Pacific railroad to a northern smelter.

The Purisima is situated 60 kilometres north of the city of Tepic, two hours' horseback ride from the Southern Pacific railroad station Corte, and is owned by A. F. Flynt, who has been doing development work during the past five years. The ore is valuable for both gold and silver. The vein is from 8 to 40 ft. wide, the ore assays \$12 to \$15 per ton across the vein, and there is said to be 'blocked out' some 50,000 tons of ore. A steam-hoist and crusher have lately been installed at the mine, and additional cyanide tanks and a Wilfley concentrator are being erected at the mill, increasing the present capacity to 25 tons per day. No ore has been stoped, all the ore milled originating from the development work, which has paid the expenses of operating the property. The Southern Pacific railroad will be opened as far as the city of Tepic on January 15, 1912, establishing a direct connection between California and the city of Tepic, a trip of about three days, and there is no doubt that this district will receive considerable attention in the near future.

General Mining News

ALASKA

JUNEAU

The Alaska Mexican G. M. Co. in November made a gross production with an 'estimated realizable value' of \$55,522, against \$55,285 for October. Operating expenses were \$28,367 in November, against \$31,894 in the preceding month, leaving operating profits of \$27,154 in November and 23,391 in October. Construction expenses amounted to \$3195 in November and \$7221 in October, leaving net profits of \$23,959 and \$16,170 for the respective months. The average yield was \$2.91 per ton of ore in November and \$2.76 in October.

The Alaska United G. M. Co. in November made a gross production of \$92,344 'estimated realizable value,' from the Ready Bullion and 700 Ft. claims, against \$114,770 in October. Operating expenses were \$53,198 in November, against \$52,069 in October, leaving operating profits of \$39,150 in November and \$62,701 in October. Construction expenses in November amounted to \$3147, and in October to \$7482, leaving net profits of \$35,999 and \$55,219 for the respective months. The average yield in November for the Ready Bullion claim was \$2.32 per ton of ore, against \$2.62 in the preceding month, and for the 700 Ft. claim \$2.45 per ton in November, against \$3.07 in October.

The Alaska Treadwell G. M. Co. in November made a gross production of \$154,578, 'estimated realizable value.' Operating expense amounted to \$89,835 and construction expense to \$14,885, leaving a net profit of \$49,858. The average yield was \$2.46 per ton of ore. The October report has been published.

ARIZONA

GILA COUNTY

The Summit mine, formerly known as the Gibson, which was under option to the Summit Copper Co. for \$442,375, has reverted to the original owner, The Gibson Copper Co. The latter company has a few men at work to keep the mine unwatered, but it is reported that actual development will not be undertaken for several months.

PINAL COUNTY

The Magma Copper Co., supposed to be controlled by Thompson & Gunn, is reported to be developing a large deposit of ore from which an average sample assayed 50% and 60 oz. silver per ton. The sample was obtained on the 800-ft. level. The ore is being shipped to the El Paso smelter.

CALIFORNIA

CALAVERAS COUNTY

Protest against the Penn M. Co.'s smelter at Camp Seco has been lodged by A. H. Keir, secretary of the Farmers' Protective Association, and a delegation of farmers from Amador, Calaveras, and San Joaquin counties, with the supervisors of the last-named county. Press accounts state that the Calaveras and Amador boards are waiting to see what action the San Joaquin supervisors will take.

MONO COUNTY

The Tonopah M. Co. is reported to be negotiating the purchase of the Landy mine, owned by the Crystal Lake company.

NEVADA COUNTY

(Special Correspondence.)—The North Star Mines Co. declared a Christmas dividend of 8%, making a total of 17% on the capital stock disbursed during the year. The payment in 1910 amounted to 23%. The reduction for the present year is credited to greater depth at which the ore is mined, less production, and heavier operating costs. It is understood the company is planning for the opening of ore in the Massachusetts Hill mine, one of its main holdings. Considerable work has been performed during the year at the Cincinnati Hill group, but results were not altogether satisfactory, according to reports. The company acquired control of the Champion mine, Nevada City district, and installed machinery, including an electric

pump, with a capacity of 750 gallons. The Champion is expected to prove one of the best properties of the company. The Pennsylvania M. Co. has placed its new 10-stamp mill in commission. Good ore is being opened in the lower levels, where an important discovery was made some months ago. The unwatering of the Midas mine will commence soon, and the steam pumps have been inspected and everything is in readiness to start. The shaft will be sent 100 ft. deeper. J. W. Young, of Sacramento, has a six months' option on the property.

Grass Valley, December 31.

The Murehie G. M. Co. and Murehie Extension G. M. Co. property was sold December 29 at sheriff's sale to the Pacific Gas & Electric Co. for \$10,000. The sale was to satisfy a judgment of the South Yuba Water Company.

PLUMAS COUNTY

Valuable ore was discovered recently in the Brown Bear mine, about fourteen miles east of Quincy.

SACRAMENTO COUNTY

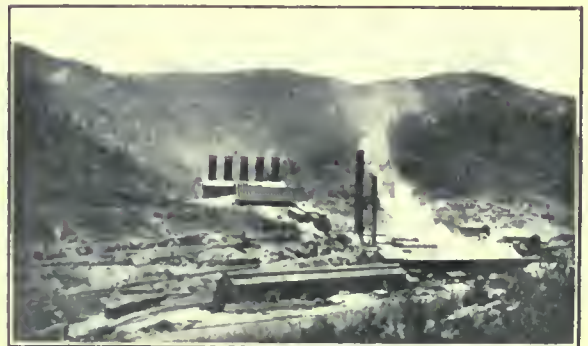

Frank Griffin was elected president of the Natomas Consolidated of California at a directors' meeting December 28 in San Francisco. Eugene De Sabla, who retired from the presidency on account of the pressure of other business, was elected vice-president.

SAN FRANCISCO COUNTY

The annual meeting of the San Francisco Stock Exchange was held January 8. A. B. Ruggles, president of the Exchange, reported that the oil and stock exchange transactions for the year closed amounted to more than \$36,000,000. Officers were reelected as follows: A. B. Ruggles, president; William Edwards, vice-president; J. J. McKenzie, secretary; C. D. Laing, treasurer. Messrs. King and Landon, respectively chairman and assistant secretary, also were chosen to serve another year.

SHASTA COUNTY

(Special Correspondence.)—The Bully Hill Copper Co. is reported to be contemplating the early resumption of

MAMMOTH SMELTER, SHASTA COUNTY.

activities at its Delamar smelter. It is said an electrical process will be employed to recover zinc and copper content. The company conducted extensive experiments with the electric iron-smelter at Heroult last summer, and results were understood to be encouraging. The Bully Hill mines are the deepest copper properties in the county, having been developed to a depth exceeding 900 ft. The ore carries zinc, gold, and silver. The General Electric Co. of New York is largely interested in the company. The Delta Consolidated is planning increased activities with the advent of spring. Shipments of gold bearing ore recently made to the Mammoth smelter yielded fair profits. The ore is silicious and finds a ready market at Kennett. S. D. Furber recently assumed charge of the property. It is stated the German syndicate which acquired the Evening Star mine several years ago is arranging for an early resumption of activities. The mine is situated in the Old Diggings district, a few miles west of Redding. George H. Bayha is resident manager. Deep development at the Reid, another Old Diggings producer, will commence early in the new year. The Shasta Copper Exploration Co. is prospecting the Stowell claim and contiguous territory ad-

joining the Balaklala estate. The tract lies in the section situated between the Mammoth and Iron Mountain properties, and gives considerable promise. Alden Anderson and associates are reported to be planning development at the Trinity group of gold claims. The property is equipped with a 2-stamp mill, and it is understood a larger plant will be installed. The Glenn County M. Co. is preparing to erect equipment on its holdings in the Dog Creek district. Lessees opened good-grade ore during the summer, and prospects are encouraging. The Noble Electric Copper Co. has completed three large electric iron-furnaces at Heroult. Pig iron will be produced in commercial quantities in the coming year.

Redding, December 30.

SIERRA COUNTY

(Special Correspondence.)—Abe Hall, the new superintendent of the Tightner Mines Co., has taken charge of the property, and is outlining plans for development. Sufficient ore is blocked out to keep the plant operating for several months, and it is understood the lower workings will be crowded ahead to open the Red Star and other veins to considerable depth. The snowfall, thus far, has not hampered work. The Sixteen-to-One company has taken a lease on the Nissen mill, owned by the Tightner company. High-grade ore is being crushed. The mill at Plumbago, controlled by the Croesus M. Co., is running largely on ore from the winze in adit No. 4. Progressive development is under way and considerable new territory has been recently opened. The power ditch has been reconstructed and other surface work accomplished. C. W. McMeekin is manager. It is reported that the Rainbow company is planning work along advanced lines during the coming summer. This was formerly one of the best properties at Alleghany, but the shoot was lost about a year ago. The property is equipped with a 10-stamp mill. Denver people principally are interested, and L. P. Woodbury is manager. Other Alleghany companies report plans for progressive work with the new year. The lack of sufficient water has forced the closing of the big hydraulic mines at Seales and Brandy City. The snow has partly blocked a portion of the ditch system, and unless heavy rains set in, considerable difficulty will be experienced in operating the gravel properties. The Neocene at Seales, and the Brandy City, are two of the largest active hydraulic mines in central California. The Oro Fino company is rapidly completing its 5-stamp mill at the Oro Fino mine, on Hopkins creek, near Downieville. The Johnson concentrators have been installed. The vein averages around 20 ft. wide, consisting of quartz, schist, and porphyry. The adit has been driven 550 ft. The ore is said to be of fair grade.

Alleghany, January 6.

TULARE COUNTY

Newspaper reports state that a deposit of pure feldspar, used in glass-making, has been found near Globe, on the upper Tule river, by agents of the Pacific Glass company.

TUOLUMNE COUNTY

(Special Correspondence.)—The Columbus mine has been sold for a cash price, the buyers being wealthy San Francisco men. The property is situated about three miles northeast of Tuolumne and has been idle for a number of years. Work was started on January 6 with a small crew of men. Some machinery will immediately be installed, a new head-frame erected, and the shaft repaired, after which it is the intention to sink 200 ft. deeper. T. G. Winwood is temporarily in charge of operations.

Complete operations will be resumed at the Shawmut before long, the overhauling and repairing of the large plant being about finished. A contract has been let for cutting a raise in the Jumper from the 500-ft. level north to the 200-ft. level. Development work is being done in various parts of the mine, and the shaft is being repaired below the depth of 200 feet.

The Rising Sun mine at Arastraville, owned by D. A. Porter of Los Angeles, is being unwatered and will be examined by Thomas Wilkinson of Los Angeles. The

McAlpine mine, south of Jamestown, has been unwatered and development work is now in progress. The Clio, of which M. D. Kelly is superintendent, is now in full operation, the mill having just been started.

About \$40,000 will be expended in surface equipment at the Black Oak mine. Some work is being done at the Mammoth, one of the group of claims owned by the Republican M. Co., commonly spoken of as the Republican mine.

The Climax mine, near Stent, owned by C. A. Fitzgerald, has just been examined for Los Angeles capitalists. The body of rich ore that was exposed by a cave on the 400-ft. level drift in the Providence mine has been opened in several places. Some of the ore is remarkably rich.

Tuolumne, January 6.

William H. Scott has bonded the Mayflower mine to W. P. Daniels, of Wonder, Nevada.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—The compressor plant at the Bellevue-Hudson mine on Columbia mountain was brought into commission today, and a force of 15 to 20 men will be given employment. J. J. White has secured possession of the Ramsdell property on Lincoln mountain. A company is now in process of organization. Work on the Rosebud group of claims is progressing, a 4-in. streak of gray copper ore having been uncovered in the lower adit. Assays show 125 oz. silver per ton. G. W. Teagarden is manager. A. D. Bryant, leasing on the Everett mine, has found a 6-in. streak of ore that shows wire silver. Assays show 700 oz. silver per ton.

Georgetown, January 1.

(Special Correspondence.)—The production from the Idaho Springs district for the past year is given as follows: gold, \$656,612; silver, \$176,375; copper, \$69,400; lead, \$60,057; zinc, \$44,390; total, \$1,006,834. There is little difference from the preceding year. It is reported that the Lucania M. & T. Co. will resume work in the advance of the adit. W. W. Kirby is manager. R. R. Graham and H. B. Baker have taken a five-year lease on the property of the Chicago Mountain M. & T. Co., situated on Chicago creek. The raise from the lower level of the Blue Ridge mine is nearing completion. Ore shipments will start inside of thirty days. P. H. Stanhope is manager. The Hoosae adit on Fall river is being driven steadily forward. E. D. Quigley, the manager, states that a mill will be constructed next spring. Work will be resumed in a few days on the Honest John adit up Chicago creek. The bore is in a distance of 2200 ft. J. F. Puchert is manager.

Idaho Springs, January 2.

OURAY COUNTY

Newspaper estimates place the production of gold, silver, lead, and copper in this county for 1911 at \$3,829,792.

The Brown Mountain Smelting Co. has an option on the Ouray smelter and will operate it as a custom plant. Thomas B. Crawford, of Denver, has announced that a lead furnace of 50 to 100 tons capacity will be added to the equipment. The main part of the ore treated probably will come from Mr. Brown's properties.

SAN MIGUEL COUNTY

Press estimates of the production of vanadium in this county for 1911 place it at \$1,884,000, against \$630,000 for 1910. Shipments of ore and concentrate amounted to less than last year, largely due to interruption of traffic to the Durango smelter. The number of cars shipped was 1602, of which 1068 were from Telluride.

TELLER COUNTY (CRIPPLE CREEK)

Arthur Carnduff, of Cripple Creek, has obtained a lease on the Dead Pine claim, owned by the Ophir M. & M. Co., and the Crown Point claim, owned by the Crown Point G. M. Co., on Battle mountain.

Exceptionally rich ore recently was found in the Kalamazoo mine on Bull hill, according to report. James Gigen, of Altman, is one of the lessees operating the mine.

The South Burns has resumed operation after a shut-down of over a month.

The Vindicator Con. G. M. Co. has declared its regular quarterly dividend of 3c. per share, payable January 25.

The recent cold weather has in some instances frozen the air-lines in the district, says a press report. Owing to the freezing of water, in pipes supplying the boilers of the Logan shaft-house, the compressors there had to be shut down for two days.

IDAHO

BLAINE COUNTY

The Wilbert M. Co., Ltd., has been financed through Deru & Thomas, of Salt Lake City. The mill is almost completed and it is hoped it will be in operation before March.

SHOSHONE COUNTY

The foundation of the compressor of the Black Horse M. Co., near Murray, has been completed, and the compressor will be erected in a few days. The property is to be in full operation during this month. J. Thennes is manager of the property.

A 250-ton concentrator is to be erected at the Tuseumbia mine, on Beaver creek, nine miles from Wallace, says a recent report. The property, which is near the Hercules mine, recently was purchased by G. A. Lauzier, Paul Wolcott, and W. J. Dawson of Butte, Montana.

MONTANA

The present depths of the principal mines of the Anaconda Copper Mining Co. are as below:

	Feet.		Feet.
Diamond	2900	Pennsylvania	1800
High Ore	2800	Leonard	1800
Neversweat	2500	West Colusa	1800
Original	2500	Badger State	1800
Anaconda	2400	Buffalo	1500
Gagnon	2400	Moonlight	1500
Mountain Con.	2400	West Gray Rock	1300
St. Lawrence	2300	Silver Bow	1000
West Stewart	2300	Berkeley	1000
Mountain View	2200	East Colusa	900
Tramway	2000	J. I. C.	600
Belmont	2000		

The depths of the shafts of other Butte mines are:

	Feet.		Feet.
North Butte	2800	Raven	1500
Tuolumne	1800	Butte-Ballaklava	1500
Butte-Alex Scott	1800	Pilot Butte	1300
Colorado	1700	Ophir	1000
Butte & Superior.....	1600	Elm Orlu	1000
East Butte	1500		

FLATHEAD COUNTY

(Special Correspondence.)—J. H. Ehlers, in charge of the extensive mining and water-power development work at Yakt falls, in the extreme northwestern part of the State, has interested Eastern capitalists in the great amount of timber suitable for paper pulp in the Yakt watershed, and expects to have these men on the ground early next summer to perfect plans for a large sawmill and wood-pulp plant in the vicinity of Yakt falls, where electric power will be developed. His plans include building an electric railroad in the Yakt basin and the use of the most modern electric logging and manufacturing appliances in utilizing the immense stands of timber in that locality. It is expected to develop 3400 hp. at the falls, which will also be used in the operation of the mines at Sylvanite. Mr. Ehlers has just returned to Spokane after a visit to Libby in connection with this work.

Libby, January 7.

SILVERBOW COUNTY

(Special Correspondence.)—An attempt is to be made in behalf of the shareholders in the United Copper Co. An organization called the United Copper Securities Co. has been incorporated under the laws of the State of Maine, with a capital of \$4,000,000. The evident purpose is to form a stockholders' pool in the shares of the United Copper

Co. Present holders are asked to accept notes, in part exchange for stock, which is to be held by a trustee as collateral for the payment of the notes; when a market is made and shares sold, the excess above a certain upset price is to be divided, one-half to be for the purpose of rehabilitating the subsidiary companies of the United and one-half to go to the depositing shareholders. If the new organization can get far enough into the heart of the United Copper Co. to make an inventory of its assets so that outside stockholders may know what their certificates really represent, they will have accomplished what has so far proved an impossibility.

Butte, January 6.

NEVADA

CHURCHILL COUNTY

The new mill of the Nevada Wonder M. Co. was temporarily shut down recently on account of the cold spell, which through contraction of the steel pipe-line sprang a leak. By cooling the compressor with the cyanide solution on hand, the agitating-vats were kept 'alive', although other machinery was stopped and two shifts were laid off at the mine.

ESMERALDA COUNTY

The Continental Development Co. is about to start work at the Yellow Top and White Jacket groups of claims, say advices from Goldfield. J. E. Meyer is general man-

PART OF ESMERALDA AND NYE COUNTIES.

ager and Lewis Cruikshank, of Los Angeles, secretary for the company, which is reported to have purchased 587,000 shares of Yellow Top stock.

At a miners' meeting at Antelope Springs, the name 'Antelope Mining District' was chosen to designate that part of the county. The district is to extend from the spring north six miles, east four miles, south six miles, and west six miles. A regular wage-scale is to be adopted, and it is thought \$5 will be selected. A recorder, sanitary committee, and other officials for the district were chosen. The boundaries of the district were chosen by a committee of old-timers. The Jordans, represented at the meeting, have 225 sacks of ore from the original 'find' ready for shipment.

E. Perrier de la Batne has purchased the Orleans group of five claims in the Hornsilver district, south of Goldfield. Development will be started this spring.

Reports from Goldfield state that the Tonopah M. Co. is to buy the Lucky Boy property, situated in the Lucky Boy district.

LINCOLN COUNTY

The Virginia Louise M. Co. has been organized to operate the Louise claim at Pioche. Portland capitalists are reported to be heavily interested in the property. William Lloyd is president of the company.

LYON COUNTY

J. K. Cameron and F. J. Wilson, lessees operating on the upper levels of the Ludwig mine of the Nevada-Douglas Copper Co., will start shipping ore to the Mason Valley smelter in the near future.

The first furnace of the Mason Valley Mines Co.'s new smelter at Thompson was blown in January 6. The smelter has a capacity of 800 tons of ore per day. Construction was started in November 1910, and it is said that almost a million dollars has been expended on the plant. It is expected that of the ore treated, 500 tons will come from the Mason Valley mine.

MINERAL COUNTY

Unauthenticated reports say that the Tonopah M. Co. has purchased the Aurora property, on which it has held a lease. The same report states that the company is negotiating the purchase of the Lundy mine, situated in Mono county, California.

NYE COUNTY

(Special Correspondence.)—It is currently reported that the Montana-Tonopah company has struck a rich vein on the 800-ft. level, the deepest working point. The vein is said to be 6 ft. wide, with 15 in. rich ore. Estimates of the ore range from \$80 to \$1000 per ton. Rumors credit the discovery as the most important in the history of the property. Officials admit the intersection of good ore. On the 465-ft. level the Triangle vein has widened to about 4 ft. Ore is being stoped from the A. B. K. vein on the 615 and 665-ft. levels. The South, McDonald, and Mizpah Fault veins are also reported to be improving. The Tonopah Extension has recently opened good ore in the western portion of the property. The principal reserves are situated in the eastern section, but development in the extreme western section is progressing vigorously. The North Star company has levied an assessment of 2c. per share to provide funds for additional work. Considerable development work is going on. It is believed the new vein recently opened in the Montana may extend into North Star estate. An option on the unmined stock of the Tonopah Gypsy Queen M. Co. has been taken by San Francisco, Goldfield, and Tonopah capitalists. The property adjoins the Montana on the east and the North Star on the south, and embraces three claims and a fraction. It is reported A. B. Ruggles, president of the San Francisco Stock Exchange, will be selected as president. The Priest mill has been purchased by C. E. Webb, of Philadelphia, and will be operated by the Peak-Steen-Cicala lease on Manhattan Big Four. A recent milling of 1072 tons at the War Eagle plant averaged \$24 per ton. The vein is said to be 25 ft. wide on the 300-ft. level, and has been tapped at the 400-ft. point. A tube-mill will be added to the War Eagle plant, increasing its capacity to 70 tons per day. The mill is idle pending repairs. The discovery of commercial coal at Coaldale, 30 miles north of Tonopah, is causing much interest. Two veins have been found, one 11 ft. wide.

Tonopah, January 7.

STOREY COUNTY

The Ophir company last week produced 387 tons of ore valued at \$11,904. Ore in the 2100-ft. level stope has decreased in value, but still is profitable. The sill floor, south drift, 2100-ft. level, was extended 13 ft. and timbered. The south drift, west cross-cut, 2400-ft. level, was extended 16 ft. through ore of low assay-value. The shipments for the week included 346 tons of second-class ore.

The Ophir M. Co. on January 10 declared a dividend of 10c. per share, payable January 25 to stockholders of record on the 15th. The dividend will mean the disbursement of \$20,160.

The Mexican mill has resumed operating on 'waste rock'. One shift per day is worked in the mine.

General repairs were made in the Union shaft and the winze used jointly with the Sierra Nevada company.

The southwest drift, 2550-ft. level, of the Con. Virginia was advanced 20 ft. The face is now in vein formation.

Pumping operations were carried on as usual at both

the C. & C. and Ward shafts. In addition to repairs at the Ward, a drill-hole was sent 64 ft. from the raise on the 2000-ft. level without finding the old workings. On the 2200-ft. level cutting out ground has been started preparatory to cross-cutting beyond the bulkhead. After present preparations in the Julia winze, a relay blower will be installed to permit exploration in the old workings. Operation will be resumed soon in the Brunswick No. 1 shaft. The east cross-cut, 1200-ft. level, of the Overman, was extended 9 ft. Work was resumed at the Gold Hill mines. The Yellow Jacket mill finished run No. 4, making 520 tons for the week, and one earload of concentrate shipped to the smelter. Repairs were made to the Yellow Jacket shaft. The Belcher resumed work on the 1400-ft. level.

A committee of miners selected from the grand jury to investigate the conditions underground of the Chollar Leasing Co., whose operations were claimed to endanger a school-house, stated that the structure was in no danger, and that the company's maps of the workings were correct. Development of the property, it is reported, will be resumed in the near future.

The De Sabla-Slosson pool, at the Savage stockholders' meeting, January 8, wrested control of the company from the Leonard interests. H. L. Slosson was elected president, W. C. Ralston vice-president, and Whitman Symmes superintendent. The board of directors is composed of A. F. Coffin and W. B. Bannan, of the old directorate, and Messrs. Slosson, Ralston, and C. B. Sessions.

WASHOE COUNTY

C. E. Maek and George Green, of Reno, will operate the Reno-Mizpah mine in the near future, according to recent newspaper report. They had a judgment for \$370 on the property, and bought it for that sum at a creditors' sale.

WHITE PINE COUNTY

The Gold King Mining & Milling Co. has been organized to develop 21 claims on Ruby Mountain, which were located by Joseph Mayer. August Munter is general manager for the new company, states a report from Ely.

The American Rare Metals Co. has been incorporated at Salt Lake City to develop six tungsten ore claims about 75 miles east of Ely. Jeremiah Nolan is president, J. T. Burns vice-president, and C. L. Olson secretary-treasurer of the company.

Exploration work on the property of the Ely-Nevada Copper Co. was taken up recently under direction of Fred H. Strelke. Ten men are reported to be employed.

NEW MEXICO

LINCOLN COUNTY

The Wild Cat Leasing Co. has purchased from the White Oaks company the mill built at the latter company's property at Nogal at a cost of about \$100,000. The Wild Cat has started hauling the equipment to White Oaks, where its property is situated.

OREGON

BAKER COUNTY

A series of lectures on mining geology is to be given at Baker by the mining engineering department of the Oregon Agricultural College, beginning January 29. These will be illustrated with a large number of mineral ore and rock samples and with several hundreds of photographs.

UTAH

JUAB COUNTY

A new orebody recently was opened on the 300-ft. level of the No. 2 workings of the Colorado mine, state press reports. Work has been resumed in the Richmond & Anaconda mine, which has been idle for about eight years. The operations will be through the Unele Sam mine. Both properties are being developed by the Unele Sam Con. M. Co., for which C. C. Griggs is superintendent.

The Eagle & Blue Bell M. Co. has completed preparations for shaft-sinking. Three shifts will be used, and it is ex-

pected that progress will be made at a rate of about 135 ft. per month.

The recent discovery on the 1600-ft. level of the Grand Central has been followed for 150 ft. The management will drive still farther to develop the ore before raising or sinking.

The power plant at the portal of the Holden adit has been put in operation to supply power to the Centennial Eureka pump, which has been getting power from the Knight company.

TOOELE COUNTY

At a meeting of the stockholders of the Lion Hill Con. M. & M. Co., on January 6, arrangements were made for supplying the company with at least \$2000 per month for development expenses for the next 15 months. October 15 was selected as the date for exchanging stock in the company for stock in the Lion Hill Con. Mines Co., which will take over the property together with claims purchased from the Buffalo Con. M. Company.

WASHINGTON

SPOKANE COUNTY

Recent reports state that bills modeled after the Kansas 'Blue Sky' law will be presented to the legislatures of Washington and Oregon at their next sessions. These proposed bills, which are to require all corporations to give detailed and thorough information to the bank commissioner of the State, who will then pass on their legitimacy, will be discussed at the Northwestern Mining Convention, to be held in Spokane, February 15 to 17.

CANADA

BRITISH COLUMBIA

A contract has been let for doing 2000 ft. of development work on the No. 6 cross-cut adit of the Sloean Star mine, which it is reported will be on a producing basis by the first of the year.

ONTARIO

A 5-drill compressor and three hoists have been ordered for the Gold Reef property, formerly known as the Clark Syndicate claims, at Porcupine. Sixteen men are employed.

MEXICO

CHIHUAHUA

(Special Correspondence.)—Milling was resumed at the La Republica by the Compania Minera la Republica, S. A., December 1, after a shut-down of four months, and normal production will be resumed in the near future. The shut down was caused by the floods of the last rainy season.

Chihuahua, December 29.

Arturo Longega has purchased the America, Monte Cristo y Anexas, and Abundancias properties in the Guamaecvi district from Antonio Sanchez. The price is reported to have been \$40,000.

The Rio Tinto smelter has resumed after a shut-down of three weeks. The fire in the Veta Colorada mine has been extinguished with the loss of part of the timbering.

The American Smelters Securities Co. is building an experimental plant at its Tecolotes mill. The plant will be equipped with two Elmore vacuum-process separators, for treating zinc middling.

The Europa M. Co., S. A., has been organized to develop the Europa property, Parral district. The property, which consists of 18 pertenencias, recently was purchased by L. W. Knotts.

The San Cristobal M. Co., Parral district, is considering the erection of a mill. B. V. Gordon, manager for the company, recently was in New York to confer with the directors of the corporation.

HIDALGO

(Special Correspondence.) In 1905 the properties of the Compania Real del Monte y Pachuca were acquired by the United States S. R. & M. Co., which operates an extensive list of mines and smelters in the United States. Up to the present the Mexican operations of the company

have been confined to the Pachuca and Real del Monte districts. However, in the last few months their engineers have been making examinations in many parts of Mexico. In order to facilitate the work of an energetic campaign of enlargement in the Mexican Republic, offices have been opened in the Mutual Life building, in the heart of Mexico City, for the receipt and consideration of all data regarding mining properties which may be in the market. This office and the field work in Mexico will be directed by Ezequiel Ordoñez, as geologist. The management of the company's interests in Mexico will remain in the hands of C. W. Van Law, the director of the Compania Real del Monte y Pachuca.

Pachuca, January 5.

SONORA

(Special Correspondence.)—A stampede is in progress to the head of La Cañada and Baboyohui rivers, about 40 miles southeast of Navajoa, Sonora, as a result of the recent rich gold discoveries made in these streams. The gravel is said to average \$2.50 per cu. yd., and in many places bedrock dirt has been found that is reputed to be worth from \$35 to \$40 per cu. yd. Many prospectors are going into the new diggings and are cleaning-up from \$10 to \$15 per day with a pan. Mining men who have been over the ground are favorably impressed. Coarse gold has been found in the beds of these streams for hundreds of years by the Indians, who make their living picking up gold after every rain. Most of the ground on the La Cañada river has been taken up, but there is still 15 or 20 miles of rich bedrock on the Baboyohui river that can be located. Most of this gravel, it is believed, will average better than 40c. per cu. yd. The conglomerates on each side of the rivers are also rich. There is plenty of water in these streams at the present time for sluicing. The National Placer M. Co. of Navajoa, recently organized to work a group of 30 claims on the headwaters of the La Cañada river, is preparing to build a dam in a narrow canyon near the head of the property for the purpose of storing enough water for hydraulic purposes. When this plant is complete, this company intends to handle between 8000 and 10,000 cu. yd. of gravel per day. San Francisco people have secured a group of seven claims joining the property of the National Placer M. Co. on the south, where the Cañada river empties into the Baboyohui river, and have erected gasoline pumps and are meeting with good success. They are handling gravel that averages better than \$2 per cubic yard.

Navajoa, January 1.

L. Kelly, formerly with the Calumet & Sonora company, has taken a lease on part of the Cananea-Boston M. Co. property near the Catalina No. 2 shaft. He is erecting a lead-frame and hoist, and plans active development. The Cananea-Boston company is concentrating its work on the northwestern part of the property, and has the shaft there down nearly 200 ft., according to recent reports.

Ore assaying about \$1000 per ton in gold was discovered a short while ago at the Santa Rosalia. The Corriente placer property, Altar district, has been sold for \$125,000 to Californians represented by U. F. Bender, of Tucson, Arizona. On December 6 the Amelia mine, near Noria, reverted to its former owners, the Holt brothers, of Magdalena.

NICARAGUA

According to Frank York of Kentucky, part owner of the Cypress mine in the Pis Pis district, exceptionally rich ore is being mined at that property. The Panama M. Co. is working only 12 hours per day at present, owing to a shortage of men and difficulty in getting wood.

SOUTH AMERICA

According to the Hamburg *Fremdenblatt*, the German Transmarine Electricity Co. of Berlin has concluded a contract with the Argentine Government, or the Petroleum Commission appointed by the latter, whereby almost the whole of the production of petroleum near Comodoro Rivadavia, in the south of the Argentine Republic, will devolve upon the company.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

H. S. GALE is in San Francisco.

S. C. HEROLD, of Tonopah, is in town.

F. L. SIZER has returned from Montana.

W. H. STORMS has gone to Los Angeles.

* C. W. PURINGTON has been in St. Petersburg.

JOHN B. FARISH was in San Francisco recently.

B. C. AUSTIN, of British Columbia, is at the St. Francis hotel.

J. F. KEMP was at Butte recently and has returned to New York.

COURTENAY DE KALB was in San Francisco and has gone to Oregon.

JAMES F. PARK is superintendent at the Plymouth mine in California.

WILLIAM KNOX will be in San Francisco January 25 on his way to Siberia.

CHARLES C. MOORE and CURTIS H. LINDLEY have gone to Washington, D. C.

WALTER W. BRADLEY has been appointed librarian at the State Mining Bureau.

E. K. SOPER, of Minneapolis, Minnesota, was in San Francisco for Christmas.

FREDERICK HELLMAN, who lately returned to New York from Europe, is in the West.

FRED T. WILLIAMS has returned to Park City, Utah, from New York and Washington.

M. N. SHORT, formerly of Natoma, California, is at Santa Barbara, Chihuahua, Mexico.

KARL P. SWENSEN has been visiting mines in Japan, but will return to Nanking, China.

H. A. MORRISON is assistant manager for the Uwarra Mines Co., at Candor, North Carolina.

I. ROGOVIN has resigned his position as editor of *Gold and Platinum* to resume private practice.

E. L. LEPPER is doing field work in Eldorado county in the employ of W. J. SEABORN, of Berkeley.

R. E. SMITH and D'ARCY WEATHERBE are examining platinum placers near Ekaterinburg, Russia.

GELASIO CAETANI is in British Columbia, and expects to return to San Francisco at the end of the month.

GEORGE E. COLLINS will leave New York January 13 on the *Oceanic* for a short business trip to London.

H. KENYON BURCH spent the holidays with his family at Los Angeles. He has returned to Globe, Arizona.

F. G. LASIER will be at Cripple Creek and Salt Lake City in January, returning to Detroit about February 15.

SYDNEY L. SHONTS will make San Francisco his headquarters hereafter. His address is 1418 Larkin street.

HENRY F. LEFEVRE has returned to New York from Central America, and will remain there until the latter part of February.

F. M. FREEBORN has returned from Mexico to engage in practice as consulting metallurgist, with offices at Alhambra, Los Angeles.

H. C. WILMOT sailed on the *Manchuria* for the Philippines, where he will be engaged in professional work for several months.

C. B. WHITWELL has opened an engineering office at Marysville, California, under the name of the Whitwell Engineering Company.

W. H. YEANDLE has been transferred from the position of assistant general superintendent of the mining department of the Cia. Real del Monte y Pachuca, and is now connected with the exploration department of the United States S. R. & M. Co., rooms 411 and 412, Mutual Life building, Mexico City.

Report of the Oriental Consolidated Mining Company for 1910-11

The report of this company for the year ended June 30, 1911, is replete with interesting detail. The main features are summarized in the table below. The profits were greater than for any preceding year, and despite the large amount of ore treated, the reserve has been increased in all the mines except the Chintui, and Kuk San Dong. The company, it will be remembered, owns a concession covering 600 square miles in the Wunsan district of Korea and has opened a number of mines besides maintaining necessitated minor readjustments in the affairs of the company and has involved the management in some anxiety though Mr. Perkins apparently is satisfied with the prospects of a satisfactory outcome. He says truly, and appropriately: "The company's officers are quite in sympathy with the Government officials in their desire to protect the forests of the country; the use of timber and wood is of vital necessity if the mines are to be operated. In view of the friendly attitude heretofore of the Japanese au-

towns, local railroads, and other incidental enterprises. It is the largest business organization in Korea, and prior to establishment of Americans in the Philippines was the principal American outpost in the Far East. In all, 2,598,812 tons, valued at \$15,954,358, have been mined and treated.

Dividends for the year under review totaled \$641,985, and the surplus at the close was \$561,146. The total ore reserve is estimated by the general manager, Alf. Welhaven, at \$802,280, valued at \$3,851,770, and a force of native prospectors is kept steadily at work in the effort to develop additional mines. The president of the company, H. C. Perkins, notes that a settlement of disputed questions regarding wood and water rights has been reached on the basis of the company paying 25,000 yen per year as a reforestation tax. Evidently the transfer of authority from native hands to the Japanese Government has

thorities. I am confident that some method will be found which, while protecting the forests as far as possible, will enable the company to pursue its operations without being called upon to submit to harassing regulations or unduly onerous taxation. The position of the Oriental Consolidated Mining Co. is exceptional—it is the pioneer in successful working of the low-grade mines in the Far East. Its enterprise was undertaken in the belief that the existing government regulations would not be essentially changed to its detriment. It has established an organization that is an excellent mining school for the people of the country, and has set an example of honest and successful mining practice that is attracting capital to Korea. In view of these circumstances, I have confidence that we will receive every proper consideration from the Governors of the country in adjusting the wood and other problems that may come up."

Among the Copper Mines

Since 1900, it is said, the world production of copper has increased 73% and the consumption 77 per cent.

The Mohawk M. Co., Keweenaw county, Michigan, with copper selling at 14c., may increase the dividends to \$2 per year, according to late reports. It has been paying \$1.50 with copper at 12½ cents.

The Chino Copper Co., Grant county, New Mexico, over a period of four weeks through one section of the mill, recently treated an average of 850 tons of ore per day. The yield averaged 66% from oxidized surface ore assaying 2.75 to 3% copper, the ore coming from the Whim Hill part of its holdings.

D. C. Jackling recently stated, after a personal inspection, that the Chino is producing 1,000,000 lb. of copper per month with one section of the mill in operation. The yield is 40 lb. of copper per ton of ore, which is oxidized as the workings so far are near the surface. He stated that the December production of the Ray Con. Copper Co. would be about the same as the November production, 2,650,000 lb. of copper.

Boston reports are to the effect that supposed representatives of the General Development Co., controlled by the Lewisohns, have seemed further extension of option on the South Side, Dacotah, Naumkeag, and Montezuma properties, just west of Houghton, Michigan. It is believed the properties will be taken over by a new corporation already organized, in which only the underwriting remains to be done.

The North Butte M. Co., while going through the Butte 'lean streak,' has maintained a production of 2,000,000 lb. of copper per month, and dividends of \$1.20 per share per year, even with copper at 12c. The company recently opened a body of high-grade ore on one of its northern claims, from which it is shipping 150 tons per day, and has good ore on the 2600 and 2800-ft. levels, from which it hopes soon to accomplish an increase in production and earnings.

The December output of the Miami Copper Co., Gila county, Arizona, amounted to nearly 3400 tons of concentrate which should yield over 2,580,000 lb. of refined copper. Five units of the concentrator have been in operation since December 1, and the sixth and last unit is expected to be running by February 1. The ore milled during December averaged 2.6% copper, and the daily tonnage now being handled is about 2500, of which about 12% comes from the dump, 35% from square-set and sub-level caving operations, 35% from development, and the rest from shrinkage stopes. At the east side of the mine, ore is being mined by square-sets and sub-level caving, and in the northwest part by shrinkage stopes, there being in this part of the mine an available tonnage of 2,740,000. The total developed tonnage above the 420-ft., or first tramming level, is over 9,000,000 tons. Development keeps pace with mining, averaging 4000 ft. per month. The cross-cut from the main shaft, on the 570-ft., or second tramming level, is in 475 ft. and has 250 ft. more to go to reach the orebody. The equipment of the pumping station at Bureh now consists of two Aldrich triplex pumps, each driven by a 400-hp. motor, and having a capacity of 1600 gal. per minute. An air-compressor has recently been installed to furnish air for air-lift pumping in testing some wells in the vicinity of the pumping station, one of which is now flowing at the rate of 250 gal. per minute and is increasing. The total number of men employed is over 700, of whom 370 are employed underground, 120 in the mill, and the rest in the power-house and shops. B. B. Gottsberger is general manager, N. O. Lawton mine superintendent, and F. W. Solomon, mill superintendent.

Book Reviews

Any of the books noticed in these columns are for sale by, or can be procured from, the **MINING AND SCIENTIFIC PRESS.**

THE MINING INDUSTRY OF MEXICO. Compiled and edited by F. Gonzalez, A. Grothe, and L. Salazar S. No. 2, State of Hidalgo, Part II. Pp. 108. Maps and plans. Mexico, 1911. For sale by *Mining and Scientific Press*. Price, \$1 postpaid.

This is a continuation of the comprehensive work on Mexican mines and mining of which the first number has been noticed already. It maintains the high standard set by the opening number, and contains accounts of mines at Pachuca, Zimapán, and Jacala.

EXPERIMENTAL ENGINEERING, AND MANUAL FOR TESTING. By R. C. Carpenter and Herman Diederichs. Pp. 1132. Ill. John Wiley & Sons, New York, 1911. For sale by *Mining and Scientific Press*. Price, \$6.

This is the seventh edition of a standard work and contains much that is new. Indeed, the whole book has been thoroughly revised and rewritten and is now up to date in every particular. To mechanical engineers the book has long been favorably known, but mining engineers have not profited as much by it as they might have done. To them it may be stated that it covers in a broad way the underlying principles and the methods of testing materials and machines in general engineering. Exclusively metallurgical, electrical, and like problems are not touched, but the field covered includes problems of the use of fuel, lubricants, structural materials, power generators, and a wide variety of special engines. The mining engineer is often called up to work alone and must be prepared always to understand and often to make the simpler tests of the sort mentioned. To him, therefore, the book will be extremely valuable for reference at the same time that for mechanical engineers it is a text.

THE AUTOBIOGRAPHY OF JOHN FRITZ. Pp. 326. Illustrated. John Wiley & Sons, New York, 1912. For sale by *Mining and Scientific Press*. Price, \$2.

This is one of the most interesting and delightful stories of achievement that has been given the public in a long time. To write an interesting biography, it has been said, one must have an experiencing nature. He must be of the class to whom all happenings are events and most events are adventures. Surely no class of men have more material at hand for making good autobiographies than have engineers, and yet too few of them have written of their lives for other people. Probably it is because the unusual becomes usual to them and they lose the sense of novelty. Fortunate indeed is the man who hangs on to the spirit of youth and sees always with the eager interest of a boy, however much he may estimate as a man. John Fritz is one of these fortunate ones, and a wide circle of admirers are fortunate in that his intimate friends have persuaded him to write and make public this story of his life. It is a plain story of a simple, rugged, self-made American. Of one who, fortunate in his time and place, had a hand in the doing of great things in the iron and steel industry. We shall not spoil the story by quoting, and the 'Father of the Iron Industry' is so well known that the outlines of his life are already of record. What is given now conveys the flavor of the man himself. It is characteristic, after all, that he should 'have the fun' of doing this himself instead of depending on a Boswell after death. It is as when he revoked the provision in his will leaving money for the building of an engineering laboratory for Lehigh University, and then pitched in and built an excellent laboratory almost with his own hands. John Fritz, the self-made man, it may be noted, was ever the staunch friend of education, and his services to that cause are not the least among his services to his fellow men. Here's to him, may he live long and prosper, and may there be many more like him!

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

INJURY TO MINER—CONTRIBUTORY NEGLIGENCE AND ASSUMPTION OF RISK

A miner accepting employment in a coal mine assumes all the risk incident to such employment—such risks as naturally arise out of, or were necessarily connected with, such employment. It is the duty of a miner to exercise ordinary care for his own safety, and not knowingly to expose himself to unnecessary risks or dangers connected with the employment. But a miner is not guilty of contributory negligence for continuing to work in a mine or entry where the roof is not propped, where on request the operator of the mine has promised to furnish, and is required on application to furnish, props with which to prop and support the roof. In such case the miner may continue the work of mining for a reasonable length of time, unless the place is obviously unsafe. But in all such cases the question of contributory negligence is one of fact to be determined on all the evidence in the case.

Kentucky Bloek Cannel Coal Co. v. Davis, (Kentucky) 128 Southwestern, 888. June 1910.

CONSTRUCTION OF MINING LEASE

While a lease of land for the specific purpose of taking phosphate rock of a specified character and volume therefrom did not expressly covenant that such rock actually existed in the land, and while the lessee did not covenant to actually find such rock in the land, yet the contract contemplated the existence of such rock and a search therefor by the lessee, and there was an implied obligation upon the part of the lessee to make due and reasonable effort to find upon or in the land, rock of the quantity and quality specified. But what constitutes a due and reasonable effort to find the rock depends upon the fair and just requirements of the enterprise, to be determined as a fact by the application of practical knowledge and experience. A failure upon proper endeavor to find such rock was held to be a good defense in an action to recover the royalties, provided for in such lease, in the absence of an agreement to the contrary, and this was true notwithstanding the lease made provision for a minimum royalty in gross whether the mining was carried on or not, as such provision related to a failure to mine and not to a failure to find specified rock.

Hiller v. Walter Ry. Co., (Florida) 52 Southwestern, 623. June 1910.

INJURY TO MINER—INSUFFICIENT INSPECTION

A driver in a coal mine notified the inspector of a defective and dangerous place in the roof. The inspector thereupon directed a roof-man to go to the place and remove any slate or rock that was likely to fall, and pursuant to such direction the roof-man, with the assistance of the driver, made an inspection of the roof and removed the rock which from such inspection appeared to be dangerous. Notwithstanding such inspection and removal of dangerous rock, early on the following morning, without any intervening cause, slate fell from this particular place and struck and killed the driver. In an action for damage for his death it was held that the statement of the inspector concerning the inspection and the removal of the rock could not be accepted as conclusive of the fact that the mine owner, a corporation, had fully discharged its duty to keep the mine in a reasonably safe condition. If proof of such an inspection were conclusive, then in all like cases the master would be absolved from liability if he can prove that the place or appliance was examined and inspected shortly before the injury and found to be reasonably safe for the use of the servant. Especially would this be true where there is no evidence to show that the inspection was not made, or to contradict the evidence as to the extent or degree of care in making the inspection. If this were the law then, when a servant is injured or killed

by a defective appliance or an unsafe place, the master would be freed from liability by the uncontradicted evidence that an inspection had been made and that no change had taken place between the time of inspection and the accident. On the contrary, the jury may be authorized to believe from the physical facts shown in evidence that, as the roof fell soon after the inspection, a proper and careful inspection was not made, or, in other words, that the master did not exercise ordinary care to put and keep the place in reasonably safe condition.

Huddleston v. Straight Creek Coal Co., (Kentucky) 128 Southwestern, 589. June 1910.

Montana Gold and Silver Production

Gold and silver bullion to the amount of \$143,979 was received at the Government assay office at Helena, Montana, during December, according to the December report of T. B. Miller, assayer in charge. Of the above amount \$143,106 was received from the Montana counties, each county contributing as follows: Beaverhead, \$66; Broadwater, \$270; Chouteau, \$39,743; Deer Lodge, \$283; Fergus, \$20,222; Granite, \$1672; Jefferson, \$171; Lewis and Clark, \$6048; Lincoln, \$78; Madison, \$70,031; Missoula, \$1577; Park, \$55; Powell, \$369; and Silverbow, \$2504.

California Oil Dividends

During the month of December 1911 dividends paid on California oil stocks amounted to \$820,070. The largest single dividend paid was by the Union Oil Co., the amount being \$183,387. Of this sum, \$139,218 was repaid to shareholders by the United Petroleum and the Union Provident. The Union's dividends have reached a total of \$9,907,192. The totals of the United Petroleum and Union Provident were \$3,139,896. Of the December dividends, \$134,500 was English money paid to the Imperial, Gypsy, and Mountain Girl, which were sold to British capitalists. The following is the table of dividends:

Company.	Rate.	Amount.
Amalgamated	\$1.00	\$50,000.00
*Buick	0.04	127,252.16
Caribou	0.025	8,070.30

Catalogues Received

AMERICAN SPIRAL PIPE WORKS, P. O. Box 485, Chicago. 'Lap Welded Steel Pipe.' 32 pages. Illustrated. 8 by 10 inches.

INGERSOLL-RAND Co., 11 Broadway, New York. Form 4108, 'B-104, Sergeant Rock Drill.' 4 pages. Illustrated. 6 by 9 inches.

GENERAL CHEMICAL Co., 25 Broad street, New York. 'The New Herreshoff Furnace.' Bulletin No. 2. 12 pages. Illustrated. 7 by 10 inches.

ELECTRIC WEIGHING Co., 183 Thirteenth avenue, New York. Bulletin describing the 'Electric Weigher,' for recording the weight of material flowing over conveyors.

THE WEBSTER MFG. Co., Tiffin, Ohio. 'Webster Method.' November issue. 26 pages. Illustrated. 6 by 9 in. Describing installations of conveying equipment made by this company.

THE ALEXANDER MILBURN Co., Baltimore, Md. 'The Milburn Light.' 48 pages. Illustrated. 6½ by 9¼ in. The Milburn acetylene light for mines, quarries, steam-shovels, search lights, etc., with full details and prices.

NEW YORK ENGINEERING Co., 2 Rector street, New York. 'Empire Gold Dredges.' 68 pages. Illustrated. 6½ by 10 in. A handsome catalogue giving full information about the Empire dredge, the Empire prospecting drill, and the Empire mechanical tailing elevator.

KEYSTONE PLACER DRILL Co., Beaver Falls, Pennsylvania. 'The Rescue of Joseph Clary.' An interesting booklet telling of the rescue of a miner from a mine near Joplin, Missouri, where a Keystone drill was used to find him and to furnish food, etc., until he was rescued.

ROBINS CONVEYING BELT Co., Park Row building, New York. Bulletin No. 47. 80 pages. Illustrated. 6 by 9 in. A description of typical ore and material handling plants in large mining and smelting operations, in which the use of conveying machinery has reduced operating costs.

ALLIS-CHALMERS Co., Milwaukee, Wis. Bulletins No. 1523, 'Portable and Stationary Air Compressors'; No. 1524, 'Price List of Repair Parts for Auxiliary Air Brake Apparatus'; No. 1625, 'The Hydro-Electric Development of the Great Northern Power Co.'; No. 1800, 'The Richards-Janney Classified.' All 8 by 10½ in. Illustrated.

SULLIVAN MACHINERY Co., Peoples Gas building, Chicago. 'Mine and Quarry,' for November. The leading articles in this issue comprise the following: 'Mining Slate in Maine,' 'Michigan Coal Mining Problems,' 'Hoisting Economy for Shallow Mines,' 'Diamond-Drilling in Mexico,' and 'Portable Rock-Drills on the Havana Sewer.'

CARNEGIE STEEL Co., Pittsburgh, Pennsylvania. 'Shape Book.' Fourth Edition. 256 pages. Illustrated. 5 by 8 in. This valuable book is beautifully published with flexible leather cover, gilt edges. It contains profiles, tables, and data appertaining to the shapes, plates, bars, rails, and track accessories manufactured by Carnegie Steel Co. It should be in the library of every engineer.

ALLIS-CHALMERS Co., Milwaukee, Wisconsin. Revised index of this company's publications in force October 1, 1911. Also Bulletins No. 1074, 'Direct Current Motors and Generators'; No. 1075, 'Belted Alternating Current Generators'; No. 1077, 'Lighting Transformers'; No. 1078, 'Alternating Current Generators'; No. 1082, 'Engine Driven Direct Current Generators'; No. 1083, 'Direct Current Motors and Generators'; No. 1211, 'Feeders for Roller Mills'; No. 1519, 'Barometric Condensers'; and No. 1721, 'Trimmers, Slashers, and Cut-Off Saws.' All illustrated. 8 by 10 inches.

THE DEANE STEAM PUMP Co., 115 Broadway, New York. Bulletin D 205, 'Triplex Power Pumps.' 32 pages. Illustrated. 6 by 9 inches. An extensive discussion of the construction of its triplex power pumps of the vertical, double-acting type. It explains the advantages of the triplex ma-

chine over other forms of power pumps. The analyzed dissection of the pump, pointing out the features of design that are the outcome of this company's forty years specialization in the building of power pumping machinery, will be found of particular interest. The simplicity, durability, accessibility, and solidity of the Deane triplex power pump are points that are specially emphasized. The pumps listed range in size of cylinders from 2 by 3 in. to 12 by 13 in., and in capacities from 11½ to 2475 gal. per minute. Some nine different styles of these pumps are illustrated and tables of dimensions, capacities, speeds, etc., are given of each. The pumps are arranged for belt or gear drive from any power source.

Commercial Paragraphs

The Salt Lake office of the SULLIVAN MACHINERY Co. has been moved from the Dooly building to the Kearns building. M. G. Doll is local manager.

THE MINE & SMELTER SUPPLY Co. has been appointed sole agent for the sale of the patented Paterson agitation tanks in the Republic of Mexico.

THE OLIVER CONTINUOUS FILTER Co. reports the shipment of two 75-ton steel-tank filters to the Amparo Mining Co., Etzatlan, Jalisco, Mexico.

THE BRODERICK & BASCOM ROPE Co., of St. Louis, reports the sale of two more yellow strand ballast cables to the Government for Panama, repeating former order.

W. D. Hawkins, formerly of the Hill-Hawkins Boiler & Tank Works, is now connected with the tank department of THE KENNICOTT Co., with headquarters in the Corn Exchange Bank building, Chicago, Illinois.

ALBERT BURCH, GELASIO CAETANI, and OSCAR H. HERSHEY have joined in a firm for general practice in mining engineering, ore dressing, and economic geology, and will maintain offices in the Crocker building, San Francisco, California.

By reason of the death of A. J. Bettles the assay office and laboratory of Bettles & Bardwell, at Salt Lake City, Utah, has passed to the ownership and control of A. F. BARDWELL, who as the junior partner was in charge of the business during the past four years.

THE AMERICAN DIRECT CONCENTRATOR Co., Salt Lake City, Utah, has received an order from the Federal Mining & Smelting Co. for 128 concentrating tubes to be installed at the latter's Morning mill, Mullan, Idaho, where 119 similar tubes have been in use since May 1911.

Among the recent installations made by the AMERICAN SPIRAL PIPE WORKS, of Chicago, is that of a 60-carload shipment of 30 to 34-in. lap-welded steel pipe for the Spearfish hydro-electric plant of the Homestake Mining Co., Lead, South Dakota. The pressure on this line is approximately 3000 lb. per square inch. A portion of the line is equipped with forged-steel bolted-joint connections, the remainder with forged-steel flanges.

A BUREAU OF ASSOCIATED GEOLOGICAL ENGINEERS has been formed under the auspices of M. L. Fuller and F. G. Clapp. Offices will be maintained at 131 State street, Boston, Massachusetts, and 331 Fourth avenue, Pittsburgh, Pennsylvania. Geological examinations along engineering lines will be undertaken and analyses and tests made. The new firm expects especially to handle problems relating to oil and gas, water supplies, bridge and dam foundations, coal, cement, and ore deposits.

Weldon & Rockfield, who have been representing the JEFFREY MFG. Co. for a number of years in the southern part of California, south of Bakersfield, and in the western portion of Arizona, have changed the name of their concern to the California Machinery & Equipment Co. They will specialize in designing and equipping alfalfa milling plants, portable track, contractors' equipment, as well as elevating, conveying, and power transmission machinery, brick and cement machinery, and placer mining plants.

EXPORTS of iron and steel manufactures from the United States in 1911 amounted to \$250,000,000, according to figures furnished by the Department of Commerce and Labor at Washington. The United States ranks third, being exceeded by Great Britain and Germany.

ANNUAL meetings of two of the engineering societies were held in New York last week, those of the American Society of Engineering Contractors and the Mining and Metallurgical Society of America. Both are among the younger organizations, but both are vigorous and helpful.

SPOKANE is making preparations for a large attendance at the Northwest Mining Convention to be held in that city February 15, 16, and 17. Delegates are invited from British Columbia and the Northwestern States, and matters relating to mining on the public domain, water-power development, and similar topics will be discussed.

ANNOUNCEMENT is made of the formation of the Inspiration Consolidated Copper Company to combine the present Inspiration Copper Company and the Live Oak Development Company. The new company is to have a capital of 1,500,000 shares having a par value of \$20 each, and there is to be a \$6,000,000 bond issue. Stock is to be exchanged on the basis of one share of the new stock for two shares of the present Inspiration, and two shares of the new for one of Live Oak. This consolidation has been previously announced, but only now are details available. The merging of the two companies brings together two adjacent properties of merit and is in the interest of economy and efficiency in operation.

GOLD in sea-water has been the basis for flotation of more than one unprofitable venture, and yet, as Mr. Coghill shows in another column, figures as to the amount of gold present are none too plentiful or certain. Mr. Henry S. Blackmore, in *Cassier's Magazine* for January, discusses the evidence upon which conclusions as to its presence have been based and also the engineering problems concerned in its recovery. Wisely he assumes no responsibility for the estimates of the amount available, and in view of the scientific importance of the question and the meagerness of the data now available, it would seem appropriate that a thorough re-study of the subject be undertaken by the Geophysical Laboratory, the Geological Survey, or some similar institution.

THE second annual meeting of the president and trustees of the American Museum of Safety, held in New York this week, was made the occasion for public award of three gold medals. The first, the Travellers Insurance Company medal, went to the Pennsylvania Railway Company, it being adjudged to be "the American employer who has done the most for the protection of lives and limbs of its workmen, by means of safety devices for dangerous machines and processes." The second, the Scientific American medal, was awarded to the Norton Company of Worcester, Massachusetts, for the most efficient safety device invented during the last three years and exhibited at the Museum. The Louis Livingston Seaman medal is given for

progress and achievement in the promotion of hygiene and sanitation and the mitigation of occupational disease. The name of the winner was not announced in advance. The American Museum of Safety maintains a permanent exposition on the sixth floor of the United Engineering building, 29 West Thirty-Ninth street, New York. It is well worth a visit and the society itself is deserving of general support.

CORRECT use of proper names is the cause of much effort to those who are at pains to be precise. The rule is simple, a name should be given exactly as written by the owner, but its application to foreign names involves phonetic difficulties and many an American of foreign descent has performed modified either the pronunciation or the spelling of his name to adapt it to the Anglo-Saxon eye and tongue. Geographic names often present so much difficulty that the attempt is frankly abandoned and an English name applied that little more than approximates the native word, such as Vienna, Moscow, and Peking. Use establishes these as the correct English names. It is the more remarkable, therefore, that many well informed people have been led into referring to Korea as *Chosen*. Korea originally had two names, one applying more particularly to the northern part, the other to the southern, the latter being recognized by the natives as properly applying to the whole country. Korea, derived from a French attempt to reproduce the name of the northern part has, through use in gazetteers and atlases, become established as the English name for the country, and the fact that the Japanese Government, upon taking over the Korean Government in 1910, officially endorsed the name *Chosen* (the Japanese rendering of the name of the southern part) does not affect English usage. If we attempt at this late date to revise our atlases Japan must appear as *Nippon*, China as *Chung-kuo*, Formosa as *Tai-wan*, and so on *ad infinitum et confusionem*. To refer to Korea as *Chosen*, is therefore, the reverse of evidence of erudition.

COMPETITIVE railroad building is a feature of contemporaneous development in Central Africa, as it was a quarter of a century ago in America. There is the difference that in Africa the lines are backed by various governments and are planned with a view to political as well as commercial strategy. In many cases they will probably not pay for a number of years but the majority, just as in America, may be expected in time to stimulate a traffic that will permit some return on the investment. How seriously development is handicapped at present is illustrated by the fact that tin concentrate from Nigeria must face a \$125 per ton rate for transportation to the furnaces in England. Mr. S. H. Ball, in his account of present conditions in the Congo country, shows how intimately railway expansion is related to mineral development. In our Rhodesian and London letters further data on the mines of this far away region are given. Evidently there are considerable bodies of ore of a grade that would be considered rich elsewhere, and evidently also transportation is being provided more rapidly than is generally recognized. The expansion of the English railway lines in Africa has been watched with much interest in America, but the speed with which the Portuguese, Germans, and Belgians are building, is less generally known. Engineers returning from Benguela report that the tedious work of crossing the sea-coast swamps and mounting to the plateau has been accomplished. From the present terminus the way to the copper country is long but not difficult. In German East Africa the rails have penetrated almost to Tabora, a station on the great north-south telegraph line, and from there to Lake Tanganyika it will be a race with the Belgians building to Lukuga. Another German line has reached Mount Kilimanjaro, on the way to

Lake Victoria Nyanza. In the Congo proper, tracks are being extended rapidly. Mr. Ball's statement that within three years it should be possible to go from London to Cape Town by way of Boma and the Katanga country, will come as a surprise to many. It would be pleasant to signalize the establishment of connections by an international engineering excursion over the route.

China in Transformation

The most important item of news which has appeared during the progress of the revolution in China is the report, early in the week, by the *Times* correspondent in Peking that the abdication of the Manchu dynasty is about to take place, and will be preceded by an edict establishing a republican form of government. Presumably the Manchu court will be liberally pensioned, and retire to Jehol (pronounced 'ro-her'), where there is an Imperial residence. We have earlier discussed the cause of the revolution, but have abstained from comment on its progress, as authentic information has been scanty. British journals generally have shown a commendable insight into the situation, but their American contemporaries have been led by their desire for sensational news into the publication of inaccuracies and misstatements, for the revolution has not been sensational in character, except in its significance. The statements in French journals have been similar to those in America. But Japanese comment is most striking for its naivete. The Tokyo *Yorodzu* argues that nations, like business firms, do not "advance by neglecting opportunities," and in the *Gaiko-jihō*, Dr. Ariga, a Japanese authority on international law, urges the Japanese Government to intervene, with the object of securing in the future some advantage for Japan. Russian comment evidences a similar feeling in that country, but the obvious undesirability of foreign intervention has enabled the United States and the European powers to restrain these nations from precipitate action.

It must not be forgotten that China's foreign loans amount to about \$750,000,000 (representing an interest charge of \$37,500,000 yearly), of which very little is held by either Russia or Japan, both of those countries being also heavily indebted to European financiers. It is evident that the immediate interest of Europe lies in the securing of stable conditions as quickly as possible, and it seems probable that more profit at less trouble will be secured by lending China money to develop her resources than by attempting their development under foreign control. Germany has expended enormous sums in her 'zone of influence' in Shantung, with but little return as yet and with no indubitable evidence of the reaping of an eventual profit. The essential integrity of China is likely to be respected because it is good business. The dependencies in the northwest may be lost to Russia, but as they have never been a source of advantage to China, little disadvantage can accrue from their loss. The danger of allowing Russia to advance so near Peking is probably imaginary; she is already equally near Berlin, with no very disastrous result.

Several phases deserve further comment. The establishment of a republic by edict of the retiring monarchy is remarkable, from a Western viewpoint, and is curiously similar to the efforts of the retiring Tokugawa Shogunate of Japan, in 1868, in aiding the formation of a new government. It seems not at all improbable that Yuan Shih-kai will be elected president, though it is dangerous to prophesy what course events will take in Oriental countries. The American press generally seems to have failed to perceive that the election of Sun Yat-sen as the president of a so-called republic was little more effective than would be the election of Mr. Robert La Follette as emperor of the United States by the Fraternal Order of Eagles, for example. The

opinion has been freely expressed that the establishment of a republican form of government in China is an impossibility, but the expression of any such opinion is *prima facie* evidence of lack of competent knowledge. The government of China has always been intensely democratic, and in the 'Book of History,' compiled by Confucius about 600 B.C., such expressions as "Heaven thinks as my people think," and "The root of a nation is its people," frequently occur. Societies and guilds for the control of various phases of social and economic activity are ubiquitous, and there seems little danger that a republic would not prove feasible. But it would be likely to be non-progressive, for the reason that prompt and effective action can always best be assured by concentration of authority. China is in much the situation of the little boy who in hoeing the garden chopped down the vegetables along with the weeds. The nation suffered the Manchu dynasty so long as the central government had but little authority. But when, under the auspices of Prince Ching, Duke Tsai, Shêng Hsuan-huai, Tuan Fang, and others, the creation of a strong government was initiated, the reaction swept away everything. So long as China was isolated by lofty mountains, broad deserts, and unsailed seas, her inchoate form of government was a feasible one. Now, close pressed on every hand by vigorous and often unscrupulous competitors, her situation is critical, and wise and vigorous constructive statesmanship to create a strong and effective government is needed. Fortunate indeed will she be if the well meant attempts at national liberty do not prove her national ruin.

American Institute Affairs

Attention is being attracted in an unusual degree to the annual meeting of the American Institute of Mining Engineers to be held in New York next month. It has been one of the striking features of the conduct of that great organization that only nine members should constitute a quorum, and it is said that at times the annual meeting could not proceed until another member or two had been called in by telephone. For an engineering society of over 4000 members this is certainly an anomalous situation. That it has obtained so long, not only without protest but almost without the knowledge of the members, is a striking tribute to the general tact and ability with which affairs of the society have been conducted. Those in control have judged, and rightly, that the members have cared more for results than method. Now, however, that Dr. Raymond has retired from the secretaryship there are signs that the members are disposed to take a more active interest in the conduct of what after all belongs to them collectively. This we believe is a healthy sign of growth rather than of belligerent criticism. After all, the Institute belongs to its members and should be what they want it to be. If the members in general exhibit a keener interest in its affairs they must inevitably also assume more responsibility, and no organization can have too broad a base or too active a membership.

Important changes in the constitution have been proposed and will be voted upon at the next meeting. While these proposals have been before the Institute for many months they have neither been actively discussed nor adequately explained. Doubtless the majority of the members know too little about their purposes and probable results to vote on them intelligently, and yet beyond a brief, formal, printed statement sent to the members, nothing has been done to inform them. At none of the sessions of the Institute held in San Francisco or in Japan was the matter even brought up for discussion. It is true that the fall meeting was a professional session and that no business could be legally transacted, but an excellent opportunity

was afforded for giving those present a little friendly insight as to the business side of the institution in which they are partners. There may be the best of reasons for voting for all the proposed amendments, for our part we believe there are, but that does not alter the fact that the members are being asked to vote, practically in the dark, for an increase in dues, a grading of membership, and for other far-reaching proposals. No committee on reorganization of an ordinary business enterprise would expect to carry through equivalent proposals without a better campaign of education. This, however, is but one instance of several. No really informing statement of the finances of the Institute is available to members. That which is printed is far from adequate. This, we are sure, is merely oversight, due to a desire to reduce things to simplest terms in public statements. The officials have always been willing to give inquiring members the fullest information. It ought not, however, be left to them to inquire. Within the year, too, important negotiations regarding a possible consolidation of the Institute and of the Mining and Metallurgical Society have been conducted. What proposals were made and what rejected, and exactly why the matter came to nothing has never been made clear to the members of either organization, and in the case of the smaller society details were not even given to all the members of its council. This policy of centralization and, in practical result, 'kitchen cabinet' control, is not therefore singular to the Institute. Surely more pains should be taken to enlist the interest of members of the societies if their continued financial support is to be asked.

In the past the nominations for office in the Institute made by a committee appointed by the council, have usually been the only ones before the annual meeting, though any member or members may make nominations, provided they be sent to the secretary in writing at least thirty days before. The time of the meeting is fixed by the constitution, being the third Tuesday in February in each year. As already stated, the meeting has degenerated into a mere form. The members necessary to make a quorum are called together and business is transacted mainly on the basis of three or four hundred proxies gathered in advance and placed in the hands of some one resident in New York. Not more than ten per cent of the members even bother to send proxies, and those who do only in the rarest instances send any instructions as to how they wish their votes recorded. In the absence of instructions and competing nominations, the member holding the proxies has had only an obvious duty to perform, and has done it. The result has been surprisingly good, but it is evident that membership in an engineering society involves responsibilities and rights that have been too lightly regarded.

It is well to follow good leaders, but it is also well for each to do his share. The American Institute of Mining Engineers voted cheerfully and almost unanimously to assume a debt of \$188,000 and to place its business affairs exclusively in the hands of a small self-perpetuating board of directors. The gentlemen who have served on that board have done so with signal ability and self-sacrifice, but that does not absolve their fellow members from obligations. That they now show some disposition to recognize the facts of the situation, is, we think, hopeful. An occasional lively contest for office would do the Institute much more good than harm. It is better for the society to have its officers elected than selected.

We have no program for the Institute, and our purpose in calling attention to conditions at the present time is to urge members to take a more active part in its work. It is a great and influential organization. We confidently expect to see it grow larger and stronger with the years, and we will gladly co-operate in every effort for its good.

Mining in the Belgian Congo, West Africa, for 1911

SYDNEY H. BALL

Mining in the Belgian Congo in 1911, although marked by no large mineral output, was notable because of the commencement of copper smelting in the Katanga; the advances made in the means of transportation and communication; and important diamond discoveries. The Katanga, in the southeast portion of the colony, has been thrown open to prospecting, and its mining laws will probably form the models to be followed by the Government when in the course of the next twenty years other parts of the colony now under concession to various large companies, are opened to general prospecting. It is worthy of note that the Belgian Congo has become one of the few countries in which almost 50% of the white population is dependent directly or indirectly upon mining. The relative increase of the mining element, although due largely to the activity of the Tanganyika Concessions, Ltd., is partly due to the expansion of prospecting and mining in other parts of the colony.

TRANSPORTATION AND COMMUNICATION

The high transport costs in the Belgian Congo will presumably be lowered by improvements now under way.

Steamers to Europe.—Steamer service between Antwerp

MAP OF BELGIAN CONGO, WEST AFRICA, SHOWING MINES AND TRANSPORTATION LINES.

and Matadi, the Congo port at the head of navigation on the Lower Congo, has long been satisfactory. The three comfortable steamers of the chief steamship line (Compagnie Belge Maritime au Congo) ranging in tonnage from 5850 to 7000 tons, make the voyage in 21 days, and this company is now reported to be building two steamers of almost 12,000 tons displacement.

Railroad Construction.—The Mayombe railroad, a narrow-gauge road starting at Boma, the capital, in the Lower Congo, is being pushed northward. The road, unless it reaches the copper mines at Mindouli, French Congo (at last reports being worked) will serve no mines, though the country through which it is to pass is being prospected.

The railroad from Matadi to Leopoldville around Livingstone Rapids (250 miles long and of 29½-in. gauge) handles all traffic between Europe and the rich up-country Belgian Congo, and much of the French Congo hinterland. As traffic has outgrown the line's capacity there are rumors that the road may be double-tracked, the gauge broadened, and the running time cut from two days to one. Studies are now being made as to its possible electrification, and to the future use of oil as fuel. Between the terminus of this road (Leopoldville), and the terminus of the Grand Lakes railroad (Stanleyville), 1125 miles, travel is by steamer. The fleet on this part of the Congo river has been increased not

only by another 500-ton stern-wheeler, but by other smaller boats, one of which, a mail boat (speed 13½ knots an hour), now being built, is the gift of the present King. Better surveys and the placing of buoys in the more dangerous channels are increasing the safety of navigation on this part of the river.

The Grand Lakes railroad from Stanleyville to Ponthierville (80 miles) has been running for some three years now, and four steamers belonging to the same company regularly ply on the navigable stretch of the Congo river from the latter point to Kindu (200 miles). A fifth of 375 tons has been ordered.

The railroad from Kindu to Kongolo was completed on December 31, 1910, and is approximately 225 miles long. This road uses iron ties (almost necessary in the tropics) and connects with the navigable stretch of the Congo river

THE COPPER BELT AND LOBITO BAY RAILWAY.

from Kongolo to Bukama (405 miles), which is negotiated by steamers. One of 125 tons has already made the voyage in six and one-half days, although the deepening of Lake Kisale has not as yet been completed.

Preliminary surveys have been made of the railroad route from Bukama to Elizabethville, where the Katanga copper smelters are situated (about 300 miles). Already 179 kilometres (106 miles) of this road between Elizabethville and the Kambove copper mine is under construction and will presumably be completed in September 1912. Construction of the line from Elizabethville to Bukama, including rolling stock, is expected to cost about \$37,000 per mile. As Elizabethville was connected with Cape Town by rail in October 1910, the traveler will be able three years hence to book a passage by boat and railroad from England to the Cape by way of the Congo mouth, viewing on the way the Equatorial forest, the Katanga copperfield, and Victoria Falls. This Grand Lakes railroad will connect at Bukama with the Lower Congo-Katanga railroad, which is projected from Piana Mutombo on the Sankuru river above Lusambo. Further, the Grand Lakes railroad is now building a line from the Congo at Kabalo (50 miles above Kongolo) to a point on Lake Tanganyika opposite Ujiji (128 kilometres by boat), which, in connection with a German East African railroad, will in four or five years, form a direct route from the East Coast to the heart of Africa. The railroad from

Dar-es-Salaam westward toward Lake Tanganyika, through German East Africa, was on July 31, 1910, at Tura, 742 kilometres from Dar-es-Salaam. In another year it is expected that it will be at Tabaro (125 kilometres farther), from which point, under a subsidy granted by the German Government, it is to be pushed to Ujiji on Lake Tanganyika (about 750 miles from Dar-es-Salaam).

The Williams railroad, starting from Benguela Bay, Portuguese West Africa, and heading for the Katanga, has now attained the plateau level, and is being operated for about 225 miles. This railroad is of 3 ft. 6 in. gauge, and although having some gradients of 1:40, and curves of 130 metres radius, the journey has been made at an average speed of 21¼ miles per hour, or 17¼ miles, counting stops. From an engineering point of view, the remaining 1000 miles is comparatively easy, but whether or not this railroad is completed in three years, as some predict, will depend upon its financial backing.

Entrance to the northeast part of the colony has been facilitated by better steamer service on the Nile. Steamers leave Kosti, a station on the Cape to Cairo railroad south of Khartoum (about 5 days from Cairo), on the eighth of each month, making the voyage in about 15 days. At Redjaf a five-day portage around a succession of rapids begins, after which a second steamer is taken for four days to Butiaba, from which Mahagi, on the Congo side of Lake Albert, is about six days march. Lake Albert is thus reached in about 35 days from Alexandria.

Eleven kilometres of the permanent way of the Buta-Bambila railroad to connect the Rubi and Welle rivers in the northeastern part of the colony, is reported finished; it was the late King Leopold's plan that this should form part of the Congo-Nile route, but it presumably will be still many years before its completion.

The grandiose scheme to build a French railroad from Algiers, southeast across the centre of Africa, to connect at Stanleyville with the Grand Lakes railroad, and thus to give an all-rail route through Africa, from north to south, shows the interest foreign capital is taking in African affairs. This line, if ever built, should place Stanleyville in the Belgian Congo, at present about 45 days from Europe, within five or six days of Paris. There are thus four trans-African railroad lines under consideration; two from north to south, the French line just mentioned, and the Cape to Cairo railroad, and two from east to west, Cameroon to Dar-es-Salaam and Matadi to Dar-es-Salaam.

Telegraphs and Wireless.—Elizabethville, Katanga, is now connected with Cape Town by telegraph and for many years telephone lines have existed between Boma and Coquilhatville and Kasongo and Uvira. A telegraph line between Ponthierville and Kindu is being rapidly pushed to completion. At present wireless messages are flashed between Leopoldville, on Stanley Pool, and the end of the cable line at Libreville, on the French Congo coast. Other stations are to be established at Stanleyville and Elizabethville and intermediate points, and in two years' time it is hoped that communication will exist between all of the more important State posts.

FUEL

The company mentioned in this review last year, formed to construct a pipe-line for petroleum between Matadi and Leopoldville (that is, around the non-navigable portion of the Congo river), is actively engaged in construction, and expects to have all pipe-lines and pumps erected during 1912, or, at the latest, the beginning of 1913. Tank steamers will discharge at Ango-Ango, a short distance below Matadi, where a new harbor and tank-farm are being built. The Congo railroad between Matadi and Leopoldville recently introduced several oil-burning engines, with a saving of 50% of the fuel cost. The completion of the pipe-line should presumably partly solve the fuel question, and should cut down the running time of the Congo river boats, which now lose much time while cutting wood. With its numerous waterfalls the Congo will in the future look mainly to electricity for power. The Grand Lakes Railroad Co. has had no particular success drilling for oil to the southeast of Stanleyville, and, notwithstanding rumors,

it is believed that no exploitable coal deposits have been found in the Katanga.

COPPER

The Katanga copper field in the southeastern part of the Belgian Congo is now holding the centre of the Central African mining stage. The copper belt is about 200 miles long and contains over 100 deposits, some of which are of large tonnage. The sedimentary country rock consists predominantly of sandstone, sandy schist, and limestone. The Tanganyika Concessions, Ltd., works these mines as open-pits; the ore of the Star of the Congo mine at Elizabethville being hauled by endless ropes from three open pits. Rumors indicate that tonnages have been reckoned on development that in our West would be considered insufficient, and it is probable that the ore will more nearly run 9% copper than 12 or 14%. Notwithstanding this, it is believed that large reserves of comparatively rich silicious oxidized copper ores exist in the district. The results of the treatment of this ore in Central Africa at a profit and at a sufficient profit to give a fair return upon an expenditure of over \$10,000,000 directly or indirectly dependent upon it, is awaited with interest.

The railroad connecting Cape Town with Elizabethville (formerly known as the 'Star of the Congo' mine, but renamed in honor of the Queen of the Belgians), was completed October 2, 1910. It has branches to the limestone quarries at Mikola and the smelter on the Lubumba river (the town is known as Lubumbashie). Four trains per week, each way, go between Elizabethville and the Rhodesian border. Cape Town is now but seven days from the camp, and Europe but eighteen days farther. A railroad extension (107 miles) to the Kambove mine, one of the richest of the other copper properties, has been begun, and, as already stated, should be finished in the fall of 1912. The Kambove mine is expected to be ready for exploitation at that time. The Great Lakes route to the mine will soon be completed, and two other railroads, as mentioned above, are headed for the field. In consequence, the Katanga will eventually not be lacking in competing lines.

Upon the arrival of the railroad the next important event was the erection of the metallurgical plant. The transport of this plant after arrival in Beira (Portuguese East Africa, the port of entry for Tanganyika freight) was delayed by unusually heavy rains, resulting in many washouts on the railroad. One of the blast-furnaces (water-jackets) of 300-ton capacity (48 by 192 inches at the tuyeres) was blown in on June 30 for a day or two, and then, for what proved to be a short experimental run, from August 4 to 26; power being generated by the erection of a temporary engine. It was hoped that the power-plant would be completed some time in September. From September 16 one blast-furnace has been running continuously, according to cables to the 'Tanks' home office, and 12 tons of copper produced daily, with the expectation that this product would be largely increased in the near future. While smelting clayey and silicious ores averaging 12½% copper, a recovery of 87% is claimed, 10% being lost in the slag and 2½% in flue-dust. The fine material is giving trouble, and briquetting is being considered, as is also the possibility of electric smelting. Less is heard of the plant by which the copper content of the silicious oxidized ores was to be reduced to grains of metallic copper and later concentrated. A plant with this object in view was shipped from the United States this year, but was, at last information, still at Beira, and all efforts are evidently wisely being bent toward increasing the output by ordinary smelting.

In 1910 153 tons of copper ore was exported from the Belgian Congo, valued at \$17,400. About the first of October, 1911, 500 tons of copper arrived in London, but this was from the Kansanshi mine, just over the Rhodesian border, owned by the Rhodesia-Katanga Junction railroad (which, by the way, is now on a paying basis, owing to the large amount of transport provided by Katanga mining). Of this railroad, 75% is owned by the Tanganyika Concessions, Ltd., and 25% by the British South Africa Co. The Kansanshi mine was opened long before the

Katanga mines, and in February 1911 had about 2000 tons ready for shipment. The ore somewhat resembles the Katanga ore; European coke was used in smelting, and the slag is rumored to have run but from 1 to 1½% copper. Early in October, however, 200 tons of copper arrived at Beira, the first considerable shipment of Katanga metal, and by the end of October 1911 some copper had arrived at Antwerp. Up to November 6, 1911, the product is reported to have been 834 tons of copper. 'Tanks' shares had this year their usual spectacular ups and downs. Severe selling carried the shares to about \$9.85 (par \$4.87) on November 7, 1911, although in October 1910 they had been \$32.85; on December 13, 1911, they had risen to \$14.14.

As to the cost of this copper per pound, few data are at hand. The contract between the Rhodesian railroad system and the Tanganyika Concessions, Ltd., is said to be 1d. per ton-mile for ore (about £6 2s. 8d. per ton of copper from the mines to Beira, or say £7 2s. 8d. per ton to London, or \$1.75 per lb., not including insurance, landing charges, and selling costs). When to this must be added the cost of mining under tropical conditions, and smelting (European coke at £13 per ton is to be used at first, and the ore requires much flux), amortization, etc., the difficulty of keeping costs within the present price of copper is seen. The next year should determine whether the Katanga is to become a factor in the copper market in the next two years or at some later date.

Elizabethville, the centre of the industry, is a Belgianized western boom town lying under the tropical sun, and with Belgian and English pioneers. In a year the white population sprang from less than 100 to 1500. The Belgians have laid out some thirteen miles of boulevards; cafés surround the 'Place Royale', and the town boasts not only of a Chamber of Commerce, but also a cinematograph show, and a local mineral water company. The establishment of drainage systems and water supply is in progress; a weekly newspaper (printed, by the way, in both French and English) is being eagerly subscribed for at \$7.50 per year. Fresh meat and vegetables are in such demand that upon the arrival of trains from the South the whole cargo is auctioned off at the station. Farmers and cattlemen are settling around the town, and a refrigerating plant and flour mill have been erected. Town lots are procured through the Katanga Special Committee, the price within the business district being from \$4 to \$8 per square metre, or from \$9000 to \$12,000 per lot (about 100 by 160 ft.). Residential lots cost about \$1600. Brick buildings must be put up on these lots, and subleasing is not permitted without the Committee's permission; providentially, no one individual can acquire more than two lots. The sudden increase of population and the large shipments of machinery and supplies has naturally somewhat overtaxed the railroad, and consignments of goods are received six or seven weeks after the invoices. Native labor is difficult, not only to procure, but to keep, and at present it is almost impossible for prospectors to get enough porters to leave for the bush. This condition will presumably be partly righted by the foundation of a Katanga Labor Bureau under Government auspices.

GOLD

The State budget for 1911 for prospecting and mining was about \$310,000. The State operates in the northeastern part of the colony, its chief placer being at Kilo, to the west of Lake Albert. The product in 1910 was 876 kg. of gold, valued at about \$525,000. The product for the first months of 1911 exceeded that of the corresponding months of 1910, but to September the product is reported to have been but a little over 448 kg., indicating an output for 1911 of less than 700 kg., or perhaps \$420,000. This falling off is due to the fact that some of the richest streams have been exhausted, and to labor and food shortages. The placer ground at Kilo is of considerable extent, and, although rich pieces of float quartz have been picked up, no exploitable vein has yet been found. About \$7,300,000 of gravel, ranging in value

from \$1.80 to \$13.20 per yard, is reported to have been blocked out. The country rock is granite gneiss and granite. Hydraulic mining is being done in some of the more favorable streams, but the greater recovery is from sluices. A dredge, ordered some years ago, is still in Uganda, due to the difficulties of transport of the heavier parts. Thirty to forty whites are employed, but the black personnel, once 3000, has fallen off markedly. Supplies arrive by way of Mombasa, whence they are shipped by the Uganda railroad to Port Florence, thence by boat across Lake Victoria Nyanza to Entebbe, and from there are carried on blacks' backs some 200 miles. Considering this method of transport, the reported cost of sluicing (40c. per yard) does not seem excessive. The importance of the alluvial deposit at Nebula, about 110 miles N.N.E. of Stanleyville, was apparently overestimated. The State worked this mine in the current year, but presumably it will be abandoned in 1912, with perhaps a total output of \$20,000 to \$50,000 gold. Operations were started by the State in 1911 on the gold placer situated at Moto, about 325 miles northeast of Stanleyville. This deposit is stated to be rich.

The Société Internationale Forestière et Minière du Congo (a Belgian-American company) has during the year bent its efforts largely to prospecting, with satisfactory results. About thirty American and English engineers and prospectors and 700 blacks are employed. Toward the middle of 1911 it began to operate a rich, though rather small, placer at Kanwa, 3 miles from Nebula. An unusual dearth of water for sluicing kept the product down for the half-year of 1911, but it should be largely increased in 1912. The total gold production of the colony for 1911 will be from \$500,000 to \$600,000.

DIAMONDS

One of the most surprising developments of Central African mining in the past five years has been the finding of diamonds at widely separated points; in Bechuanaland, German East Africa, German Southwest Africa, several points in the Congo, and in Liberia. The 1910 production of German Southwest Africa was 798,865½ carats, valued at \$5,154,859.* Pipes of rock, similar to that in which diamonds occur in South Africa, have been found in the Kundulungu plateau (southeastern part of Belgian Congo) and some 35 diamonds have been washed from sands of creeks in that general vicinity. As yet, however, it is believed that no pipes have been found to be diamond bearing. A company (Kundulungu-Lualaba Co.) has been formed to prospect these pipes, erecting machinery to wash the ground in considerable quantities. This company, of which the stock is owned by the Katanga Special Committee and the Tanganyika Concessions, Ltd., has a concession of some 12,000 square miles for diamond prospecting. In 1907 prospectors of the Société Internationale Forestière et Minière du Congo (a Belgian-American company in which Thomas F. Ryan and other Americans are interested) found one diamond on the Kasai river at Mai Munene. In the past summer a prospector for the same company picked up, in a couple of weeks, on the Kambambaie river near its junction with the Kasai, 240 diamonds, weighing in toto about 39 carats, the largest stones being about a carat. Many of these stones are of excellent water-white color, others are fancy colors, deep yellows, greens, and hyacinth; comparatively few are off-color stones. The crystallization is interesting, twins being comparatively common. These stones were washed either from pot-holes in the stream beds or from sands along the shores. Since then ten diamonds have been found at another locality and several at still another. As a result, diamonds have been found in the bed of the Kasai river and in the lower courses of its tributaries for a distance of 75 miles. Search is now being carried on for the rock source. In passing, it may be stated that the Kasai river in this region has locally cut its bed, down through the flat-lying Jura-Triassic sandstone which covers such large areas in Central Africa, into the older folded and

*George F. Kunz, 'The Mineral Industry,' Vol. XIX, p. 9.

metamorphosed rocks of sedimentary and igneous origin which resemble pre-Cambrian rocks in other parts of the world. The sandstone is equivalent to the Stormberg rocks of Kimberley, South Africa, in which the diamond-bearing igneous rocks occur as 'pipes', and in this Kasai locality the diamonds may be either associated with similar chimneys or with one of the basic rocks making up the pre-Cambrian-like basement complex.

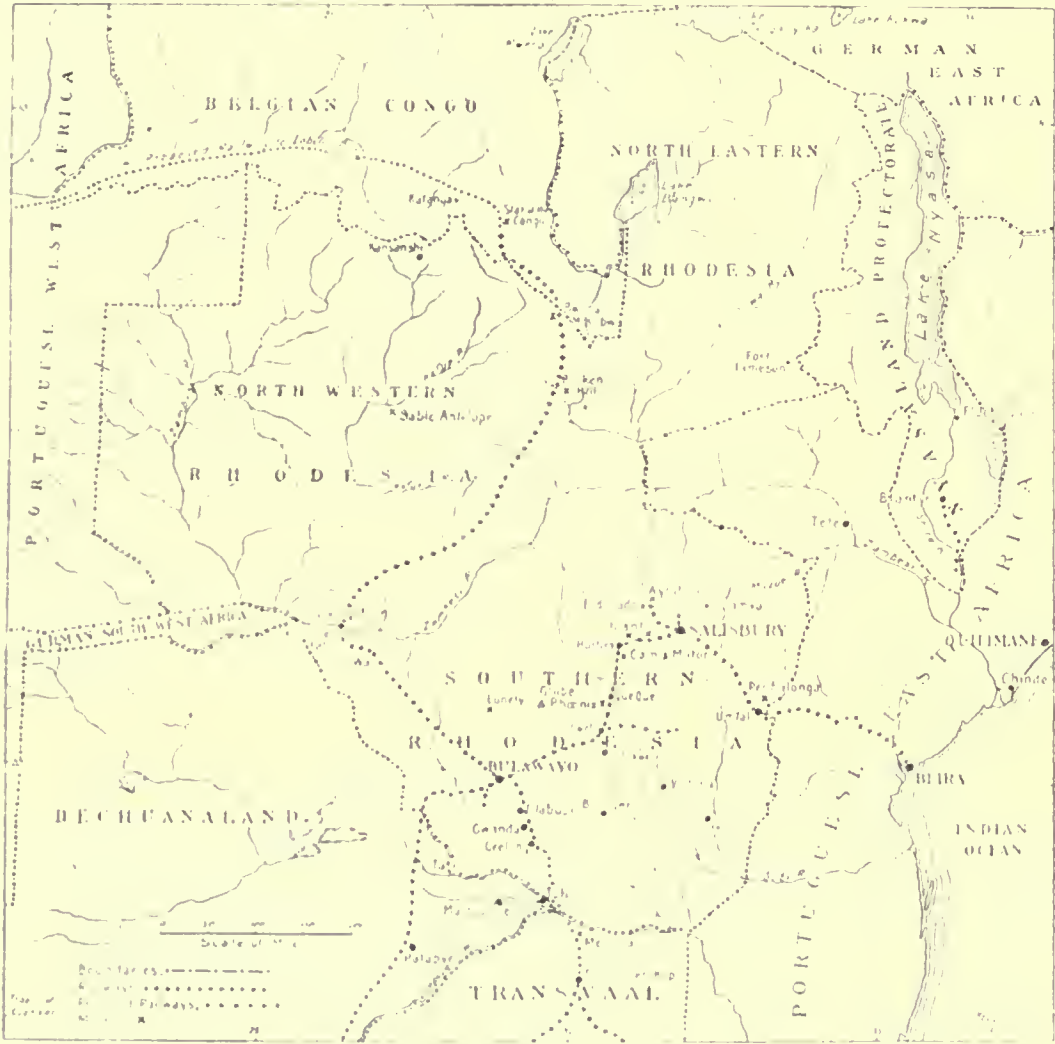

Tin

The Elizabethville-Bukama railroad, when completed, will tap the tinfield to the north of the Katanga copper belt. The tin rights over some 5000 square miles are held by

by some 60 prospectors, there being in addition some 40 independent prospectors.

Mining Laws

The mining laws published in December 1910 (decrees of December 16, 23, and 30) are of interest, as they not only open up to prospecting companies and to individual prospectors those parts of the Katanga not reserved by the Tanganyika Concessions, Ltd., but also as they will presumably form models for the mining laws of other parts of the colony, when within the next twenty years the various existing concessions lapse. In the Katanga the area reserved by the Tanganyika Concessions, Ltd., in

RHODESIA AND ADJACENT CONGO TERRITORY.

the Tanganyika Concessions, Ltd. Another company has located a supposed extension of this field.

Other Operations

The Grand Lakes railroad is continuing its search for bituminous schists in the vicinity of Ponthierville with some success, and a drilling crew was despatched in 1910 to try for oil. Its other prospectors have found numerous gold-bearing streams, none of which, however, it is believed are exploitable. Its prospecting concession upon the augmentation of its capital from 50 to 75 million francs, was increased by 4,000,000 hectares (15,500 square miles). Prospecting by the Lower Congo-Katanga railroad has not apparently been successful; some low-grade lead and copper deposits have been found, also auriferous streams. Since the Katanga has been opened to general prospecting a considerable number of companies have been formed to search for minerals in the country outside of the area reserved by the Tanganyika Concessions, Ltd. These companies have located 30 blocks, including copper, iron, gold, tin, coal, and lead, of more or less problematical value. These companies were in June 1911 represented

large blocks for one or more metals, is roughly 23,400 square miles. This is about 40% of the area covered by the older rocks which are most favorable to metallie deposits. The reservation of these blocks is the result of prospecting by the company in the whole Katanga during some ten years.

The companies already formed to further prospect the Katanga give to the Katanga Special Committee, the representatives of the Belgian Government in that part of the colony, 33% of their stock, and the same percentage of any future augmentation of capital. The committee also has the right to subscribe for 20% of the shares. In return the companies can prospect for two years over considerable areas. Prior to or upon the expiration of the two years they can take up an area, in one or several blocks, for exclusive prospecting, containing from 750 to 2500 square miles, according to the statutes of the company. They pay a yearly tax of \$200 per prospector employed. Later they can take up for mining purposes claims, none of which can surpass 38.61 square miles, nor can any one company take, in all, over 386.1 square miles. Their right to exploit expires in 1990, at which time the

mine and machinery pass to the colonial government. A royalty of 1% of gross production in the case of base metals and 5% in the case of gold, silver, or precious stones, is paid to the State, but it must, however, equal in the former case at least 4c. per acre, and in the latter \$4 per acre.

The decree of December 16, 1910, also threw open to prospecting companies and to individual prospectors those parts of the Katanga not already ceded as mentioned above. The companies (or individual prospectors) first obtain from the colonial officers for each man a general permit to prospect, at a cost of \$20, good for two years and renewable indefinitely upon new payments. Upon finding mineral indications, a paper can be obtained giving exclusive prospecting rights (cost \$40) over a circular area which in the case of precious metals or stones is 1000 metres in diameter, and in the case of the ordinary metals and non-metallie products is 5000 metres in diameter (area respectively of about 200 and 4900 acres). A discovery post must, however, first be placed at the centre of the circle with the information usually required in other countries (locality, date, name, number of license, character of discovery, and residence of prospector). The metals sought should all be listed, as only those mentioned in the location notice can later be mined. This notice is good for two years and can be renewed once upon a second payment. This permit, however, can only be delivered or renewed provisionally by the representatives of the Katanga Special Committee in the Congo, and must be passed on by the colonial legislative body, requiring the permit to go from Katanga to Brussels and *vice versa*. If this body refuses its approval the \$40 is returned, but the prospector loses his discovery, his time, and the money expended during his work. Ten per cent of the product obtained while working under this special license goes to the State. Later, a third paper, giving the right to exploit within a rectangular area, containing in the case of precious metals or stones 50 hectares (about 125 acres), and in the case of the commoner metals of 1250 hectares (about 3125 acres), can be taken out, provided the

land is vacant, is a certain distance from private and public improvements, and provided, further, that the State officials are satisfied that the company (or prospector) is financially able to exploit the deposit satisfactorily. The right of exploitation expires in 1990, at which period mine and machinery pass to the State. Thirty-three per cent of the profits go to the State. In finally locating, claim-posts must be placed at the four corners, and side-lines are to be marked by posts, each of which is to be within sight of another. Each corner-post must bear the date of the request for land, the number of the special permit, and the name in full and residence of the prospector. Payment of royalty is made quarterly, and upon receiving a permit of exploitation the prospector or company must pay the minimum tax for a quarter in advance (as above, 4c. or \$4 per acre, according to the character of the substance sought). The 33% of the profits must be paid within a month of the closing of the fiscal year of the mine. Forfeiture of the right to exploitation follows the non-payment of royalty or the stopping of exploitation, and the land reverts to the colony. If a prospector or a company wishes to cancel a claim, it can be done by first paying all royalty due and putting up a sum sufficient to cover damages which may have resulted from the mining carried on.

The best feature of the law is that no extralateral rights exist, the company or individual controlling only the ground perpendicularly beneath the side-lines of the claim. The law, considering the fact that the ground has already been prospected, and that a prospector's expenses in Central Africa are in the neighborhood of \$2000 per year, is, to say the least, not liberal to the real prospector who has developed the principal mining countries. On many points the law is obscure and, further, offers little assurance to the prospector that he will eventually get a deposit after having found it. The clause requiring sufficient capital to exploit, practically shuts out a poor man, or one with but a small grubstake, from the country, as even in case a rich placer were discovered, he is not assured permission to work it.

Iron Ore in 1911

Preliminary estimates of iron ore sold in 1911 were sent to the U. S. Geological Survey by 26 of the largest iron-mining companies in the United States at the close of the year. The combined output of these companies represents more than 80% of the total production of the United States. From these returns it is estimated by E. F. Burchard that the total quantity of iron ore marketed in the United States in 1911, not including stocks left at the mines, was between 43,000,000 and 46,000,000 long tons. This quantity represents a decrease of 22 to 24% of the sales for 1910, which aggregated 56,889,734 long tons.

Imports and Exports of Gold

According to estimates made by the Bureau of Statistics, the imports in 1911 comprised gold valued at \$11,150,000 in foreign ore, \$29,300,000 in foreign bullion, \$5,750,000 in United States coin, and \$10,050,000 in foreign coin—a total of \$56,250,000. The gold exported in 1911 was valued at \$500,000 in domestic ore, \$8,050,000 in domestic bullion, \$30,000,000 in United States coin, and \$2,250,000 in foreign coin—a total of \$40,800,000. The excess of imports over exports was about \$15,500,000, indicating a marked change from the conditions in 1910, when the excess of imports over exports was \$447,696, and also from those in 1909, when the excess of exports was \$88,793,855.

The gold imported in 1911 was mainly in the form of ore and bullion, and came chiefly from Mexico, although considerable gold is received from Canada every year and smaller amounts from the Central and South American countries, and in 1911 a large quantity of gold was imported from Japan. The exports consisted largely of gold coin and went chiefly to Canada, although smaller ship-

ments were also made to France, South America, the West Indies, and Japan.

World's Coal Output

The following table shows the coal production, in short tons, of the principal countries of the world, the figures being for 1910, except as indicated:

United States (1911)	490,000,000
Great Britain.....	296,007,699
Germany	245,043,120
Austria-Hungary (1909)	54,573,788
France	42,516,232
Belgium	26,374,986
Russia and Finland.....	24,967,095
Japan (1909)	16,505,418
India (1909)	13,294,528
China (1909)	13,227,600
Canada	12,796,512
New South Wales (1909).....	7,862,264
Spain (1909)	4,546,713
Transvaal	4,446,477
Natal	2,572,012
New Zealand (1909)	2,140,597
Mexico (1909)	1,432,990
Holland (1909)	1,235,515
Queensland and Victoria	1,119,708
Italy (1909)	611,857
Sweden (1909)	272,056
Cape Colony (1909)	103,519
Tasmania (1909)	93,845
Other countries	5,236,903
Total	1,266,981,434
Percentage mined by the United States.....	39

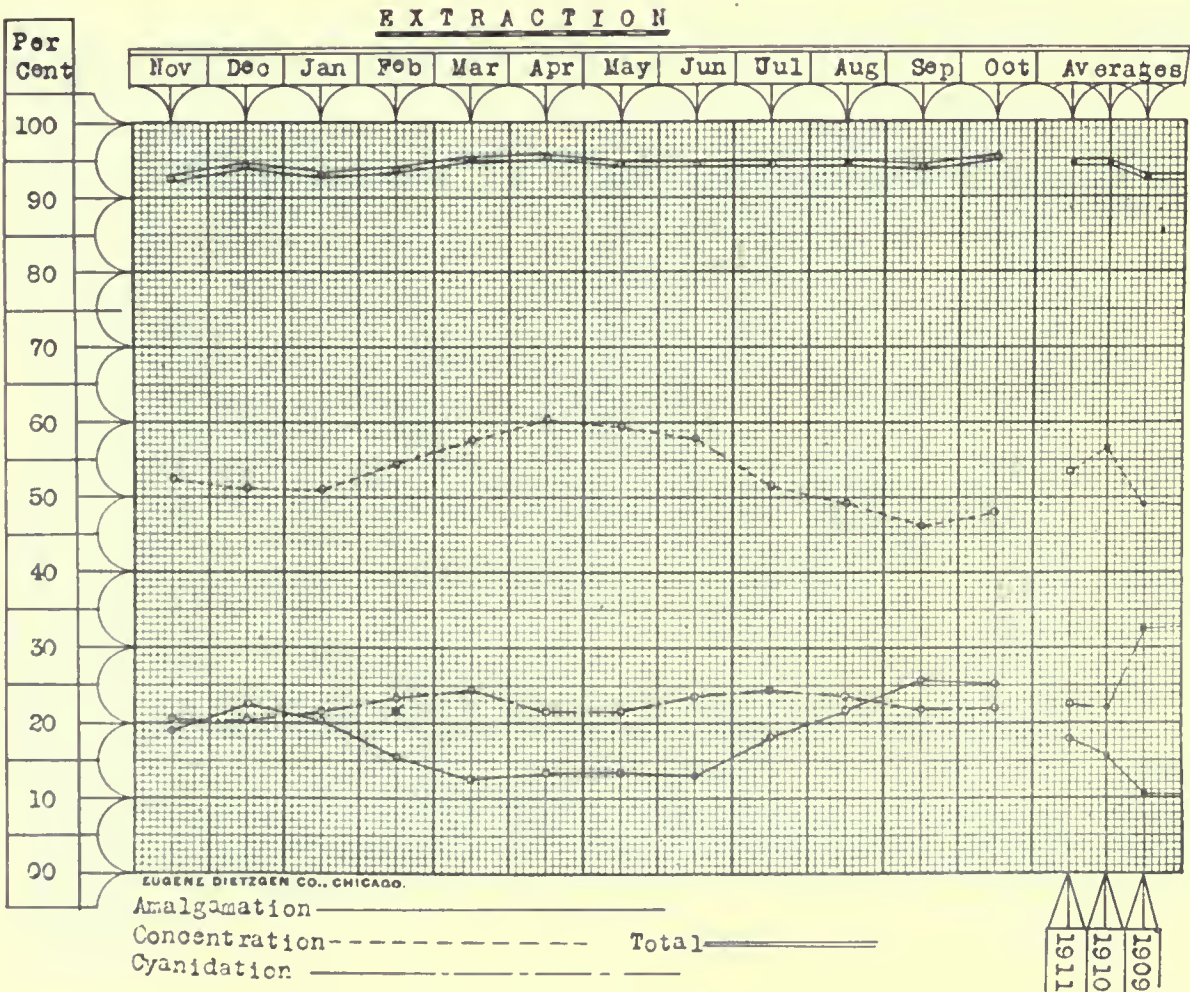

Operating Costs at the Goldfield Consolidated Mill

A detailed description of the mill used for treating the ores of the Goldfield Consolidated Mines Co., at Goldfield, Nevada, was published in the *Mining and Scientific Press* early in 1911.* In brief, the process involves three-stage reduction by means of stamps, Chilean mills, and tube-mills, followed by concentration and cyanidation, using Pachuca agitators, Butters vacuum-filters, and Merrill zinc-dust precipitation. The concentrate is treated by amalgamation and a special cyanide, or bromo-cyanide, process. Detailed figures covering operating costs for the year ended October 30, 1911, are given below, being taken from an admirable general statement of costs at the property, compiled by the superintendent, J. W. Hutchinson, and generously furnished by him to his brother cyaniders. Owing to limitations of space, only a few of the 32 charts furnished by Mr. Hutchinson have been reproduced. The figures are perhaps self-explanatory, though in considering them it is well to recall that Goldfield is a district of high wages, \$3.50 to \$5 for 8 hours work, and of high power costs, since electricity must be brought from the mountains. The cost in fact is \$6 per horse-power-month, based upon 90% of the peak load. When these figures are compared with the \$15 per year rate obtaining at some plants in Norway, or even the rates in certain American mining districts, it will be recognized that the total must inevitably be high at Goldfield. Water amounts to 220 gal. per ton of ore milled and costs 50c. per thousand gallons. It should also be noted that the ore milled is high in grade, averaging approximately \$40 per ton through two years, and the amount treated is large, about 28,000 tons per month. The actual amount treated in any month may be calculated from one of figures below, remembering that the mill includes

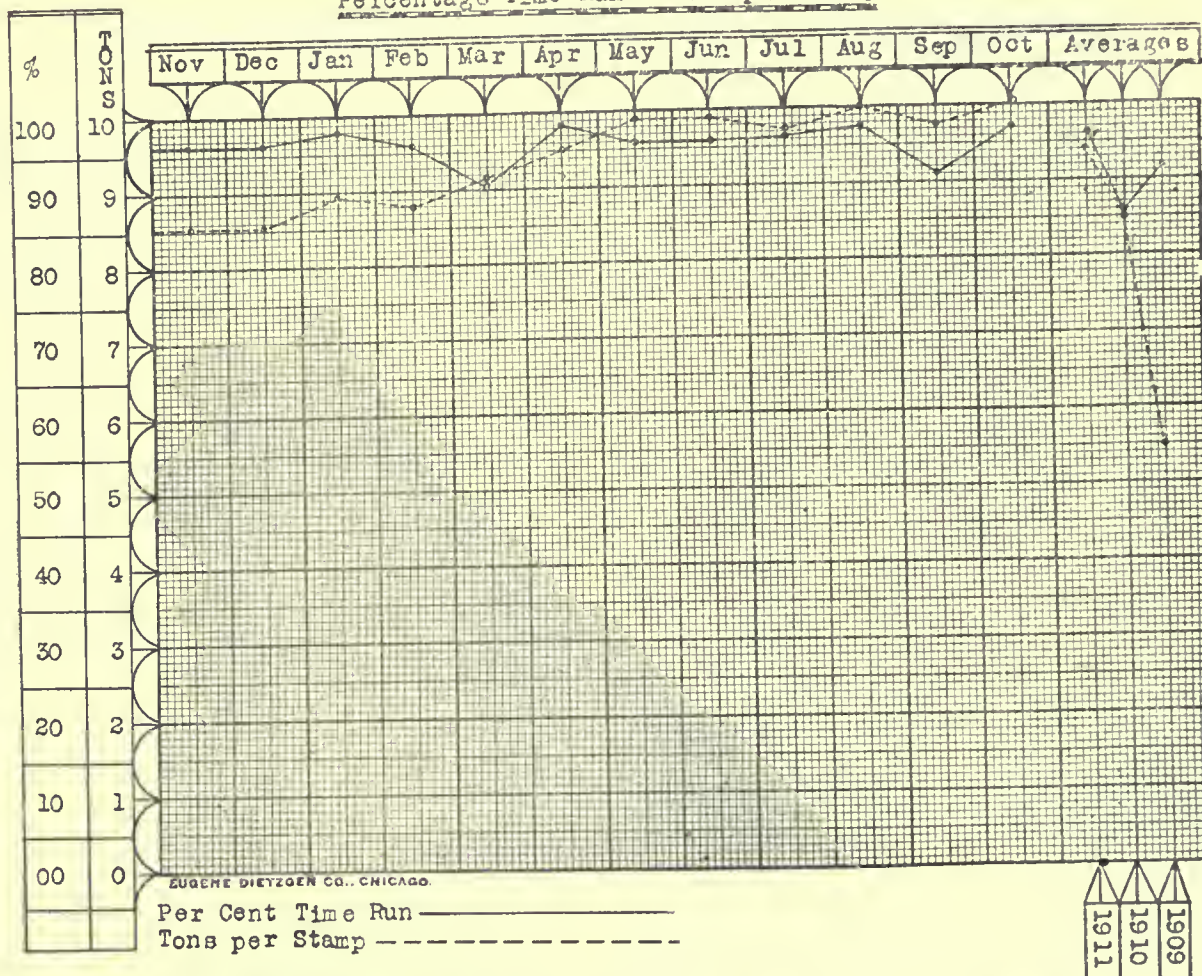

100 stamps. All the figures are based upon total tons treated. For example, the Chilean mill costs, as will be noted, ranged from 8 to 12½¢. per ton, but to get a figure for comparison with costs elsewhere it is necessary to remember that only a part of the total tonnage goes through the Chilean mills. For the actual amount, and other data, readers are referred to Mr. Hutchinson's own account of the mill, already cited. Figures for 1909 to 1911 inclusive are reproduced below.

Cost per ton milled:	1911. %	1910. %	1909. %
Crushing-conveying	0.040	0.071	0.053
Sampling	0.003	0.021
Stamping	0.134	0.174	0.195
Elevating-separating	0.022	0.023	0.021
Chilean milling	0.097	0.095
Tube-milling	0.177	0.187	0.206
Concentrating	0.057	0.059	0.062

Solution of Placer Gold and Silver

By WILL H. COGHILL

It has been recognized for decades that the gold in placers is of a higher grade than the gold in the vein from which the placer gold came. Oveido, early in the sixteenth century, commented upon this by saying: "It may be considered certain that in proportion as some washers are lower down than others, the gold will be of more carats or of greater value and fineness because the more the gold travels, the higher and finer the alloy; on the contrary, the nearer the gold is found to its vein or birthplace, the lower is its carat value." Recent publications show that there is no question about the 'fining' power of the stream, and observations in several localities show that the amount of fining varies with the distance the gold is moved. The most recent mention of the dissolving power of the stream is by W. Lindgren in Professional Paper No. 73 of the U. S. Geological Survey, in which considerable data are given, but on account of the great variation in localities no average is given to determine the amount of 'fining'. W. R. Crane¹ gives the average fineness of 800 placers and 200 quartz mines in California as 899 and 820, respectively. A calculation upon this basis would show that 107 parts of silver² was dissolved for every 1000 parts of gold present. But this is not all, for while the silver has been dissolving, the gold has also been yielding to atmospheric agencies, and the above ratio simply indicates that the silver has dissolved in advance of the gold.

Authorities seem to be pretty well agreed that the vein is the source of the gold in the sea. L. De Launay³ says: "The percentage of the gold in the sea, for the most part, must come, like all the other substances contained in the sea, from long washing to which the materials derived from terrestrial erosion carried down by the water-courses to this 'universal sewer' have been subject." Lindgren says that silver has been dissolved, and it is understood, of course, that it was carried to the sea, else he would have suggested instituting a search for silver at some point along the river. De Launay assumes that the gold in the sea comes from the vein, but may I not go one step farther and assume that the silver in the sea comes also from the same vein, and expect to find the ratio of gold to silver in sea-water the same as the relative dissolving rate? The question now arises: What is this relative dissolving rate? It is known only that the silver dissolves in advance of the gold, as shown in data mentioned above. Let us assume that this alloy is 800 gold and 200 silver. Now if this relative dissolving rate were 8 to 2, there would be neither enrichment nor impoverishment in the placer; but since there has been an enrichment, it is plain that the ratio of gold to silver in sea-water must be less than 8 to 2, providing no precipitation has taken place. This introduces a subject upon which geologists have written much—that is, the origin of gold and silver in sedimentary deposits. F. Posepny⁴ says: "As to primitive ore contained in marine sediments and precipitates, innumerable chemical analyses, especially of limestone, have failed to show the metallic traces which, according to the above hypothesis (showing that others take a different view) should be present." On the other hand, Bischof is inclined to consider hydrogen sulphide the precipitating agent resulting in the formation of lead and silver sulphides in the sedimentary rocks of the Kupferschiefer, and says: "Since it cannot be doubted that the rivers flowing into the ocean bring with them metallic salts, though in very dilute solution, it seems a wise arrangement that in the hydrogen sulphide of sea-water a precipitant is presented to throw down the small minima, and thus to prevent a gradual accumulation of substances." Many dis-

cussions can be cited in which the possibility of the segregation of gold and silver on the floor of the sea is the theme, and they go to show that an unsolved problem in ore deposits is involved. After so many discussions regarding the possibility of an enrichment due to precipitation taking place in sea-water, it indeed comes as a great surprise to learn that, according to the 'Encyclopedia Britannica',⁵ no officially authorized determination of gold in sea-water has ever been made. The statement there made by H. R. Mill and Otto Krümmel is as follows: "No quantitative determination of gold in solution in sea-water is available. Sonnstadt detected gold by means of a color test and roughly estimated the amount as 1 grain (65 mg.) per ton, and on this estimation all the projects for extracting gold from sea-water have been founded." This statement is not entirely correct, because it is said that Liversidge made numerous tests off the coast of New South Wales and found between 30 and 65 mg. gold per ton. Some Frenchmen, about fifty years ago, estimated the silver at 10 mg. per ton. It would, of course, be ridiculous to assay sea-water to determine how many million tons of gold there are in the sea, or how many gold dollars will be put in circulation by the propeller of a boat while going from San Francisco to Japan, but the determination of the ratio of gold to silver would be an advance along scientific lines. For instance, the development of an abnormal amount of hydrogen sulphide in the Black Sea has been noted. Is there any indication that it has precipitated either gold or silver? If their ratio does not approximate that in which they exist, where there is an absence of sulphuretted waters, or better yet, if the ratio does not approximate the relative dissolving rate, which is between 8 to 2 and 8 to 2, then apparently there has been a precipitation.

It seems more than strange that the assay for gold has not been made when one considers what a simple matter it is. Assuming that Sonnstadt's estimate of 65 mg. per ton is correct, 0.005 tons of solution, or 10 lb. tested, would be ample, as it would give a gold bead weighing 0.32 mg. The solids precipitated by evaporating 10 lb. would amount to 3.5% or 0.35 lb., equal to 158 gm., which could be fluxed with perfect ease, since it consists principally of sodium chloride. Such an investigation would be purely scientific, and one would not dare to predict that it would be of aid to the taxpayer, but our own Government has conducted many investigations of such nature—for instance, 'the force of gravity'—and also has carried on very expensive 'precise leveling', and is establishing bench marks in the farmers' fence-corners.

The voyage of the *Challenger* was without parallel in the history of scientific research. The staff of investigators contained specialists of every branch of science. Dittmar analyzed 77 of their samples and only mentions gold and silver, having made no quantitative test. He states that silver has been found on the copper bottoms of ocean ships; that Sonnstadt has identified cesium, rubidium, and gold in sea-water, and that C. Schmidt succeeded in determining rubidium quantitatively. One would infer from the last statement that the quantity of gold was too small for a quantitative test; this is radically different from Sonnstadt's determination. Such discrepancies or absolute lack of data indicate recklessness on the part of De Launay in his 'World's Gold' where he estimates the thousand million pounds of gold in the whole seas. If the data for which I ask are valueless, I say, then, that those who have used the figures now available as a basis of calculation and conclusions have played with figures and theories that are probably untrue, and of no value if true.

In summing up, I can state three good reasons for a series of accurate assays of sea-water: (1) It would help to give some idea as to the relative dissolving rate of gold and silver in placers; (2) comparing the data from one sea with those of another might shed some light on the theory of ore deposits; (3)—and possibly not least—it would likely put a quietus on the wily promoter who bobs up at regular intervals altogether too often, and sells stock on a new process for extracting gold from sea-water.

¹'Treatise on Gold and Silver,' p. 162.

²This is not exactly correct, as it is known that about 4% of the dissolved material consists of base metals.

Gold Mining in 1911

By H. D. McCaskey

The gold-mining industry was generally active in 1911, but early figures indicate a total production for the United States and Alaska slightly below the output of 1910. The most notable features of the industry in 1911 were the resumption of normal labor conditions in the Black Hills of South Dakota, the increased dredge output in California, development of production in the new Innokolditarod placer region of Alaska and the Republic district of Washington, continued development and prosperity of the great Goldfield (Nevada) and Treadwell (Alaska) mines, normal conditions also on the Mother Lode in California, improvement in metallurgical methods, and general increase in activity at many small deep and placer mines. Renewed interest in prospecting was shown in Colorado, although the gold output of the State decreased, owing to the gradual exhaustion of several large orebodies and to continued small decrease in production from the great Cripple Creek camp.

In addition to the yields from placers and silicious and

pyritic gold ores, notable contributions to the gold production were made from copper, lead, and mixed ores, particularly in Utah and Arizona, the mining of which was also generally prosperous in 1911. Notwithstanding a decreased output of copper in some States, due in part, as in Montana, to prearranged curtailment, the total production of copper was greater in 1911 than in any previous year except 1909. The output of lead and of mixed ores was also notably heavy in 1911.

Preliminary figures of the Director of the Mint* indicate a total domestic gold output of \$96,233,528 in 1911, against \$96,269,100 in 1910. Information from the mines, however, indicates that final figures of production and of exports of ore smelted in British Columbia and Mexico will show increases in gold output from Alaska, Arizona, and Washington.

The great bulk of the gold production from deep mines is derived from ore treated at gold and silver amalgamation mills and cyanide plants, a much smaller quantity being produced by smelting crude ore and concentrate. Nearly a quarter of the total output is still coming from gravels of placer mines, mainly by dredging in California and drifting in Alaska.—U. S. Geol. Survey Press Bulletin.

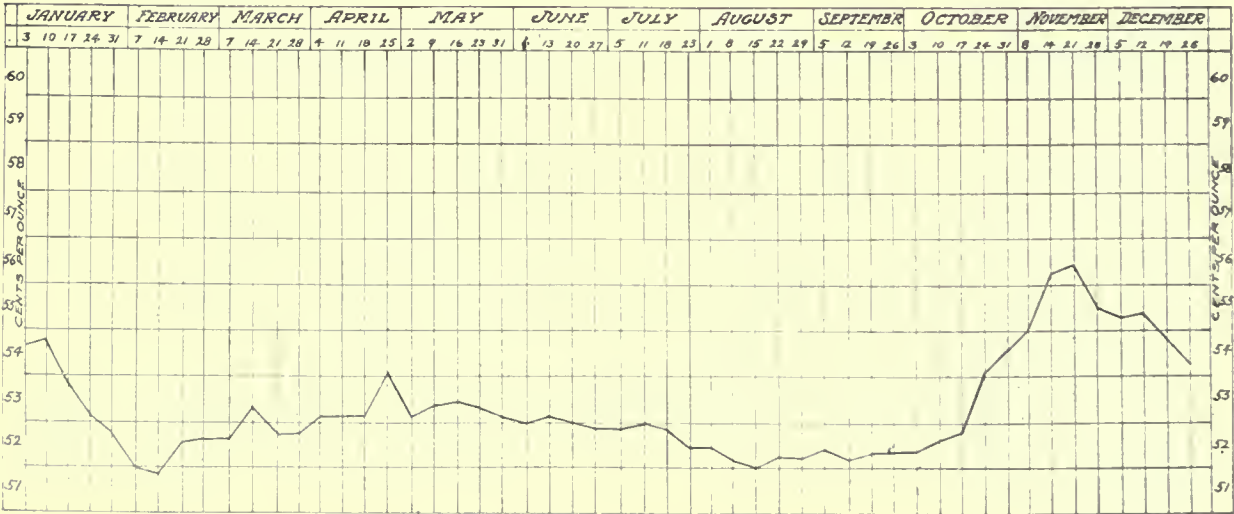

*Published In Mining and Scientific Press, January 6.

Silver Production in 1911

The silver-mining industry as such is of relatively small importance in the United States, according to H. D. McCaskey, of the U. S. Geological Survey, but the domestic silver production, depending largely on the output of gold, silver-gold, copper, and lead ores, is equal in value to that of lead or zinc. Owing largely to the prosperity of the gold, copper, and lead-mining industries, there was an output of silver in 1911 estimated at 57,796,117 fine ounces, which is 2,182,997 ounces more than the average annual output of 55,613,120 oz. of the preceding decade, and 658,217 oz. more than the output of 1910. Aside from the important production from the milling of the silver-gold ores of the mines at Tonopah, Nevada, the bulk of the silver output is derived from the smelting of crude copper, lead, and mixed ores and concentrates, chiefly from Montana, Utah, Colorado, Idaho, and Arizona and California. According to the Mint figures, the production increased from all these States except Montana, Arizona, and Colorado. In Colorado the production of all metals except zinc decreased. Increased copper production in Alaska added notably to the silver output of that Territory. Final figures will probably show increased production of silver from Arizona instead of a decrease, and possibly little change in California. Preliminary figures compiled by the Director of the Mint, and published in the Mining and Scientific Press January 6, indicate a total domestic production of silver of 57,796,117 fine ounces in 1911.

The average price of silver in 1911 was 53c. per fine ounce, a decrease of 1c. from that of 1910. The year began with silver near 54c., but the price declined to 52c. in February and fluctuated between 52 and 54c. until November, when it rose sharply to about 56c., declining to an average of 55c. for the closing month of the year. The course of silver prices through the year is shown in the accompanying figure. Speculation, chiefly in the Indian and Chinese markets, was the cause of the rise, and with the present disturbed conditions in the Far East the market may remain uncertain for some time.

According to estimates made by the Bureau of Statistics, the imports of silver in 1911 were valued at \$27,450,000 in foreign ore, \$12,850,000 in foreign bullion, \$2,150,000 in United States coin, and \$1,350,000 in foreign coin—a total of \$43,800,000. The exports of silver during the same year were valued at \$135,000 in domestic ore, \$65,000 in foreign ore, \$59,000,000 in domestic bullion, \$4,750,000 in foreign bullion, \$100,000 in United States coin, and \$600,000 in foreign coin—a total of \$64,650,000, or \$20,850,000 in excess of the value of the imports. In 1910 the value of the excess of exports over imports of silver was \$11,482,805; in 1909 it was \$11,404,607, and in 1908 it was \$9,613,541. Previous to 1908 it had not been below \$15,000,000 for several years. The imports of silver in 1911 were, as usual, chiefly in ore and bullion and came mainly from Mexico and Canada. The exports were almost wholly in ore and bullion, and went as usual chiefly to the United Kingdom and in smaller amounts to Hongkong and France.

SILVER PRICES IN 1911.

The Nevada Hills Mill

By W. A. SCOTT

The new concentrating mill and cyanide plant of the Nevada Hills M. Co., at Fairview, Nevada, was put in operation September 15, 1911. It has a rated capacity of 150 tons per day and is gradually being brought up to that tonnage. There is a descent of 120 ft. from the crusher floor to the sump floor, there being eight levels, occupied as follows: (1) crusher and elevator; (2) mill-bin and stamp batteries; (3) classifiers and concentrators; (4) tube-mills; (5) collecting and thickening tanks; (6) dilution and decantation tanks; (7) treatment tanks and filters; (8) heating plant and sump. The building, set on foundation and retaining walls of reinforced concrete, is constructed of steel, and has a covering of asbestos-lined corrugated iron, making it practically fireproof. The ore is drawn from the mine-bins over grizzlies to a 12 by 20-in. Hercules crusher, by which a sufficient tonnage is crushed in 8 hours to supply the mill for 24 hours. The crushed ore is raised to the top of the mill by a 12-in. bucket elevator, and it passes thence by gravity through an automatic sampling plant and automatic weigher into a 600-ton steel-frame ore-bin immediately above the stamp batteries. It is drawn from the bin through four Hutchinson automatic feeders, by which it is fed to the four 5-stamp batteries of 1250-lb. stamps, and these are operated in two 10-stamp sections,

NEVADA HILLS MILL.

each driven by a 35-hp. motor, belted to a cam-pulley at the centre of the section. The four mortars, weighing 12,000 lb. each, are made with narrow boxes, and designed for rapid discharge. Each mortar is anchored to a concrete foundation by seven 1¾-in. bolts of Norway iron. Each battery as a unit is designed for heavy duty, the pulp being discharged through 20-mesh screens. The present method is to pass the crushed ore from the batteries to classifiers, the fine going to 14 Deister tables, and the coarse to two 18-ft. tube-mills, 5 ft. diam.; but it is now understood that a Chilean mill is to be provided for regrinding the coarse from the classifiers, and the product of the Chilean mills is to pass through an Akins classifier, the fine from which is to be concentrated over Deister slime-tables, the coarse to be reground in the tube-mills. The tube-mill product is then to be classified by an Akins machine, the slime from which is to pass to two Dorr thickening tanks, the sand to be returned to the tube-mills for further pulverization, making a closed circuit that will permit no material to pass to the thickening tanks till it has been reduced to the requisite degree of fineness. The thickening tanks, which are 34 ft. diam., 12 ft. high, are supplied with overflow launders and heavy Dorr thickeners; the thickened pulp flows to a mixing-box, where lime-water is added, and it passes thence to nine agitating treatment tanks, each 12 ft. diam. and 32 ft. high, the clear overflow from the thickening tanks being returned by a 6 by 8-in. triplex pump to a 50,000-gal. tank near the mill. The standardized solution is put in the first treatment tank, the nine tanks being arranged in series for continuous agitation. The pulp undergoes 42 hours treatment from the time it enters

the first tank until it is discharged from the last one. A 10 by 13-in. duplex low-pressure Ingersoll-Rand air-compressor is in use for supplying air for agitation and aeration. The pulp passes from the last treatment tank through three dilution tanks, 34 ft. diam. and 12 ft. high; these are provided with overflow launders and Dorr thickeners, so arranged that the overflow from one tank passes into the next tank below it. Barren solution from the zinc presses is added in the first tank and mixed through it by the Dorr thickeners, by which the solution is diluted. The overflow, after passing to the succeeding tank, is given treatment similar to that in the first, the treatment being automatic and continuous through the three tanks; the thickened pulp is drawn off at the bottom of the last tank and transferred to the stock tank, 30 ft. diam. and 12 ft. high, equipped with a Trent agitator.

The rich solution overflowing from the last tank is passed through two 36-in. 40-frame Perrin clarifying presses to three precipitating tanks, into which zinc-dust is added by a Merrill zinc-dust feeder; the solution is then delivered by two triplex pumps to two Merrill precipitating presses, each of 300 tons capacity, situated in the refinery building. The barren solution from these presses flows to two solution tanks, from which it is drawn off and standardized.

The pulp in the stock tank, above mentioned, is drawn to two Oliver continuous filters, each 11 ft. 6 in. diam. and 12-ft. face, the filtered and washed residues discharging upon a 14-in. belt tailing-stacker 200 ft. long, running at an inclination of 20°. Vacuum for the filters is maintained by two 14 by 14-in. belt-driven vacuum pumps.

The late John B. Fleming, who designed and directed the construction of the plant, made the following statement in his report to the company: "Inasmuch as concentration, when preceding cyanidation of silver ores, is being abandoned in many cases, it should be stated that there is in this mine a large tonnage of oxidized ore containing manganese dioxide so combined with silver as to make a combination that does not yield to cyanide treatment, and concentration must be adopted to remove this mineral. When the oxidized ore is exhausted concentration probably can be abandoned."

The water supplied for mill work is pumped from the mine by two Gould's triplex pumps, each having the capacity of 100 gal. per minute, and each of which is driven by a 40-hp. electric motor. The property is being operated under the management of E. A. Julian, with J. W. Hutchinson as consulting engineer.

Paragenesis of Zeolites

By J. VOLNEY LEWIS

*Zeolites and other secondary minerals occur in the Newark igneous rocks of New Jersey: (1) in cavernous spaces in theropy pahoehoe of the extrusive Watchung basalts; (2) in fault fissures and fault-breccia of both the basalts and the great intrusive sill (Palisades, Rocky Hill, and Sourland mountains); (3) less commonly in the ordinary joint cracks of both the extrusive and the intrusive types. The rocks are practically the same in both chemical and mineral composition, consisting essentially of pyroxene and plagioclase feldspars, with quartz-bearing and olivine-bearing facies. The zeolites and related silicates are essentially combinations of the feldspathic elements and water, with the addition of fluorine in apophyllite and boron in datolite; the accompanying amphibolite, biotite, chlorite, epidote, serpentine, and talc are derivatives of the pyroxenes. Hypotheses of origin dependent on the action of meteoric waters are inapplicable on account of difficulties of circulation, deoxygenation, and sources of fluorine and boron; on the other hand, contact metamorphism by the intrusives has produced in the adjacent shales minerals into which fluorine and boron enter, presumably by emanation from the magma. Hence magmatic waters are regarded as the most probable agent in the formation of the zeolites and accompanying minerals.

*Abstract of paper read before the Geological Society of America.

A Nickel Deposit in the San Poil Mining District, Washington

By HOWLAND BANCROFT

GENERAL STATEMENT

*A reconnaissance survey of the ore deposits of north-eastern Washington was being carried on by myself during the field seasons of 1909 and 1910, during which time a great many of the properties in this part of the State were examined. The following notes on an ore deposit in the San Poil mining district are presented prior to the publication by the U. S. Geological Survey of the bulletin on the ore deposits of this part of the State because of repeated requests for information on this particular locality.

Nickel ore occurring in a deposit in the San Poil mining district has been exposed by the various workings on the Congress property. This prospect is situated on the north side of Bridge creek, $3\frac{1}{2}$ miles east of the San Poil river, the camp being at an elevation of 2500 ft. A rough wagon-road has been built from the main San Poil road to the deposit. Republic and Wilbur are about equidistant from the property, the former being a little west of north of the camp, and the latter a little west of due south, the distance by wagon-road from either railroad station being about 30 to 35 miles. The building of a railroad down the San Poil has been talked of for some time, and if completed will make the deposits much more accessible. Timber and water are plentiful in the immediate vicinity of the prospect.

Developments on the property consist of five adits, together with drifts and cross-cuts on and to the vein, and a shallow discovery-hole, totaling about 1500 ft. of underground workings. The levels are separated from each other by vertical distances of from 50 to 100 ft., and the deposit has been explored through a vertical range of approximately 300 ft. The work has been done by hand, no machinery having been installed. Shipments are not reported from the prospect. The workings are on a north-east trending offshoot of a ridge which projects southeasterly from the principal mountain mass, and slopes rather precipitously down to Bridge creek, about 1000 ft. below the crest of the ridge.

GEOLOGY

Schistose rocks of both sedimentary and igneous origin, showing considerable dynamometamorphism, constitute the principal part of the geologic section exposed in this locality. These rocks are believed to be of Paleozoic age and have been intruded by a large dike of quartz monzonite porphyry, which is exposed on the southern slope of the main ridge at an elevation of 2900 ft. This intrusive is thought to be of Mesozoic age, although it is impossible to prove that it is. Lava flows, probably of Tertiary age, cap some of the ridges, and in places extend down to the level of the valleys in the Bridge creek vicinity.

The schistose rocks have a general northeast strike, and they dip northwest at angles varying from 45 to 90°, and are composed of apparently conformable strata of amphibolitic schists with interlaminated lime shale, quartz mica schist, and a rock which resembles sheared granite. Strata of limestone and quartzite are also included in the series. As the soil covering and underbrush do not permit continuous observations of the geologic section, it is impossible to give the thickness of the various formations which, taken as a unit, probably exceed several thousand feet. Faulting is pronounced in the schistose series, and shear zones of some magnitude were seen in the workings of the Congress property. The principal faults appear to have taken place in a direction parallel to the lines of foliation in the schists, that is, in a northeast-southwest direction.

The amphibolite has probably resulted from the dynamometamorphism of a basic rock having the composition of

a gabbro or related rock magma, intruded into the sedimentary series of limestone, shale, and quartzite prior to the metamorphism of the area. The amphibolite is light green in color and is composed essentially of tremolite. The lime shale and limestone are fine grained and of a dark-gray color, the former representing a more or less impure platy limestone. Veinlets of siderite are present in the limestone. The quartzite is a fine-grained, grayish white rock showing distinct schistose structure. The rock, which now resembles sheared granite, is of a yellowish brown color and is locally distinctly schistose, especially so where it forms the foot-wall of the deposit in the Congress workings. This rock contains phenocrysts of white mica with some biotite and much talc. Magnetite, barite, and epidote are present in the rock near its contact with the schists. The intrusive quartz monzonite porphyry probably extends over a large territory and offshoots from the main dike are no doubt present in various parts of the schistose series. This rock has typical porphyritic texture, is of a general gray color, and contains phenocrysts of andesine and orthoclase feldspar with some biotite and quartz in a cryptocrystalline groundmass. Epidotization has accompanied the porphyry intrusion, and the limestones contain large quantities of epidote with which is associated magnetite and tremolite, the latter in places along shear zones being asbestiform.

ORE DEPOSIT

The deposit occupies a shear zone or fault plane in the schistose series, and consists of a quartz vein varying in width from 6 to 23 ft., which has a strike varying from N.50° E. to N.70° E., and a dip of 45 to 90° northwest. The strike and dip of the vein conform to the planes of schistosity of the enclosing walls. The quartz vein filling is of a bluish white color, is fine grained and compact, and has been so jointed that cubical and rectangular blocks measuring from a fraction of an inch up to a foot or more have resulted. The portion of the vein explored by the Congress workings is somewhat cellular, the small vugs present being filled with quartz crystals and some malachite. Talc and barite are present and form a small part of the vein filling. Sparsely scattered through the quartz are small veinlets and aggregates of pyrite associated with some chalcopyrite. These veinlets of pyrite vary in width from a fraction of an inch up to an inch or more in places, and the quartz impregnated with sparsely scattered aggregates of pyrite may extend over a larger portion of the vein. The pyrite is nickelliferous, and where oxidation has been active the sulphides have been altered and their oxidation products have been deposited as a thin film along the joint planes and fractures, and in fact along all the openings in the quartz veins. Limonite, malachite, and a carbonate of nickel are present as thin films with the result that the whole vein is discolored, the predominant color being reddish brown with scattered patches of light and dark green.

The following samples were taken by myself to determine the approximate average tenor of parts of the vein and the results of assays in this material should not be taken as indicative of a thorough sampling of the property, such sampling being quite beyond the scope of the work of the U. S. Geological Survey. A sample of a cross-cut of the vein in the lowest or No. 1 level, 390 ft. from the portal of the adit and taken 90 ft. beyond the intersection of the adit with the vein (at this place 23 ft. wide) contained¹ 0.170% nickel and 0.013% cobalt. On the No. 2 level, where the vein is cut 40 ft. from

¹Analyses for nickel and cobalt were made by J. F. Fairchild of the U. S. Geological Survey. The determinations for gold and silver were made by Ledoux & Co. of New York City.

*Published by permission of the Director of the U. S. Geological Survey.

the portal of the adit and then driven on for a distance of 160 ft. or more, a sample of 14 ft. of the vein was taken along the drift. The sample contained 0.246% nickel and 0.034% cobalt. A cross-cut at the end of this drift shows the vein to be approximately 32 ft. wide at that place. A third sample was taken in No. 3 level in a cross-cut on the vein 90 ft. from the portal, where the vein is encountered. This sample extended across 20 ft. of the vein from the hanging wall toward the foot-wall, and contained 0.120% nickel and 0.016% cobalt. The silver and gold content of the three samples was determined from a composite sample of the three. The results of this assay² show the presence of 5.5 oz. of silver to the ton and a trace of gold. A picked specimen of sulphide ore containing chiefly pyrite was analyzed for nickel and cobalt by J. F. Fairchild and was found to contain 5.71% nickel and 0.35% cobalt.

In the oxidized ores the nickel content is low, while the picked specimen of sulphide ore revealed the presence of over 5% of nickel. In view of these facts, there seems to be some possibility that this deposit may be profitably worked below water-level where oxidized material would be practically absent and where sulphides should predominate. Because of the scanty distribution of the nickel-bearing sulphide ores in the quartz vein, the ore would of necessity have to be concentrated for successful and profitable operations. The ore deposit has probably been formed by solutions accompanying the intrusion of the quartz monzonite porphyry, which intrusion has caused more or less contact metamorphism in the adjacent rocks, the evidence of which is the presence of magnetite, epidote, and barite, in the contiguous strata.

Smelter Charges in Utah

The bulk of the silver-lead ores shipped from Tintic district, Utah, to the smelters in Salt Lake valley pay a treatment charge of about \$1.50 to \$2.50 per ton, based on a certain content of lead, usually 10%. If the lead content is below 10% there is an additional charge of 8c. per unit, and if above 10% there is a credit of 5c. per unit. A charge of 12c. per unit is made on all silica, of which Tintic ores carry 60 to 80%. The shipper is debited with 25c. per unit for sulphur, 30c. per unit on all zinc over 8%, and 50c. for speiss, consisting mostly of arsenic and antimony. Iron is paid for at 10c. per unit, and in settling for the copper in lead ores the smelters first deduct 1.3% from the assay value, and about 5c. per pound from the market price on cathode copper; that is, copper in lead ore running less than 1.3% is not paid for. The producer is paid for 90% of the lead content, less 1½ to 1½¢. per pound deducted from the market price for transportation and refining of bullion. He is paid for 95% of the silver at New York prices. Based on the foregoing figures it is apparent that producers of Tintic ores pay a treatment charge of \$8 to \$10 per ton.

Most of the Park City operators pay the smelters a flat rate of \$10 to \$12 per ton, the transportation charge being \$2 per ton on crude ore and concentrate. Settlements for lead, silver, and gold in the ore are the same as those applicable to Tintic ores. Copper in Park City silver-lead ores is paid for at 5c. per pound less than the New York price, after deducting the difference between the wet and dry assay. Zinc is an important factor in the lead-silver ores of Park City, and the entire product shipped is in the form of concentrate. Most of it is shipped to Colorado and Kansas plants. Apparently the zinc situation has undergone some changes within the past seven months, and some of the zinc producers complain of exacting conditions under which zincblende concentrate is now marketed. Such a product, sampling 40% zinc, 4 to 5% lead, and 8 to 10 oz. silver, with spelter at 5c. per pound in St. Louis, is sold f.o.b. Park City at \$10 to \$12 per ton. A penalty on line is charged, and there is also a penalty if 50% of the concentrate runs finer than a certain mesh. There are no

credits for iron, nor gold, of which there is a small amount. The only mine in Park City district the ores of which are not treated on the flat-rate basis is the Daly-Judge. Its lead-silver ore, both crude and concentrated, is being shipped to the International plant, the treatment charges being figured on the silica and iron basis.

A considerable tonnage of silver-lead-zinc ore is received at the Midvale mill of the United States S. R. & M. Co. In settlement for this the producer is paid \$20 per ounce for 90% of the gold; he is paid market price for 80% of the silver, 80% of the lead, less 1½¢. per pound; 60% of the iron at 6c. per unit, and 30% of the zinc content at 2c. per pound. He pays a treatment charge of \$3 per ton, a roasting charge of \$1.50 per ton, and is charged for 10% of the silica at 12c. per unit.

Power Development in Mexico

In 10 months of 1911 the Mexican Light & Power Company, owning the big Necaxa power-plant and supplying El Oro and Pachuca, had gross earnings of \$5,793,852, and net earnings of \$3,892,412. Its subsidiary, the Pachuca Light & Power Company, in the same period had gross earnings of \$962,009, and net earnings of \$597,452. The power-furnishing capacity of the Guanajuato Power & Electric Company has been doubled by the completion of a third hydro-electric plant, on the Angelo river in Michoacan. The company has just closed a contract for the building of a 50-mile transmission line from Guanajuato to the Pozos district of that State to supply the important Angustias Mining Company. The Chapala Hydro-Electric & Irrigation Company has completed, at a cost of over \$3,000,000, a 12,000-horse-power plant at Puente Grande, on the Santiago river, 15 miles from Guadalajara. This plant will now supply the transmission line extending to the Etzatlan and Hostotipaquillo mining districts of Jalisco, and any other lines that may be built. Notwithstanding a scarcity of labor during a part of the year as a result of the revolution, the Mexican Northern Power Company has made good progress in its important power project on the Conchos river in the State of Chihuahua. For several months, more than 1000 men have been at work. The company is already ascertaining power needs in the Parral, Santa Barbara, Naica, Santa Eulalia, and other mining districts. The first half of the year saw the completion of a transmission line from the Copper Queen smelter at Douglas, Arizona, to the Lucky Tiger mine in Sonora, a distance of 72 miles. A concession for a hydro-electric plant to supply power in the Zimapan mining district of Hidalgo has been granted Mr. Andrew Mackenzie, representing Canadian capital.

Natural and Portland Cements

Natural cements differ from portland cements in the following important particulars, according to E. F. Burchard, of the U. S. Geological Survey.

Natural cements are not made from carefully prepared and finely ground artificial mixtures, but from natural limestone rock. They are burned at a lower temperature than is portland, the mass in the kiln never being heated high enough even to approach the fusing or clinkering point. Natural cements, after burning and grinding, are usually yellow to brown in color and light in weight, having a specific gravity of 2.7 to 3.1—that is, the cements weigh 2.7 to 3.1 times an equal volume of water. Portland cement is commonly blue to gray in color and heavier, its specific gravity ranging from 3 to 3.2. Natural cements set more rapidly than portland cement, but do not attain so high tensile strength. Portland cement is a definite product, its percentages of lime, silica, alumina, and iron oxide varying only between narrow limits, while brands of natural cements vary greatly in composition.

New Placer Districts in Alaska

By A. H. BROOKS

*In the summer of 1911, some placer gold was found near Red mountain, on the headwaters of the Indian river, which is in the Koyukuk River drainage basin. There are said to be about 50 men prospecting in this region, and a little placer gold was mined. The auriferous gravels of the Nowitna River region also excited some interest in 1911, though no important discoveries are reported.

The Ruby Creek region of the Yukon attracted renewed interest in 1911. Ruby creek is a small stream flowing into the Yukon from the south opposite the mouth of Melozitna river, about 200 miles below the Tanana. Gold was found in the Ruby creek gravels in 1907, and since then there has been a little productive mining each year. Considerable excitement was caused among the Yukon miners by the reported discoveries during the summer of 1911 of rich placer in some creeks located in this general region and 20 to 30 miles from the Yukon. As a consequence, there was a general movement toward the new find from the Yukon camps. These discoveries of placer gold were made in the headwater regions of Solatna river, which heads on the south side of the Ruby Creek divide and flows north-eastward to join the Nowitna, a southerly tributary of the Yukon. The creeks reported to carry gold are Glenn and Birch, both tributaries of Flint creek, and Long creek. No detailed information regarding the extent or value of these placers is at hand, but it is certain that there has been as yet no production of gold which warranted the large influx of population. On the other hand, it is known that there is a considerable area lying south of the Yukon, in which the bedrock is the schist and intrusive granite typical of most of the Yukon placer district, and that alluvial gold has been found at a number of places within this area.

Stage Milling and Fine Grinding

Double-stage milling continues as popular as ever on the Rand, and all the new mills include it, although it has been claimed that the New Kleinfontein single-stage ore reduction costs are about a shilling per ton less than those of the East Rand Proprietary and Crown Mines, where enormous sums have been spent on capital account in order to increase the percentage of extraction. It is urged in various quarters, that this extra expenditure and outlay are not in all cases compensated by the slight resulting improvement in the total recovery. Mr. Stadler, who is connected with the Mines Trials Committee of the Chamber of Mines, has during the year also expressed the opinion that the extended use of tube-mills on the Rand seems to have unconsciously led in a few instances to fine grinding, quite beyond the economic or payable limit. Any grinding beyond a certain point, he points out is unnecessary, because it not only fails to assist, but may tend to impede the recovery of the gold, and at all events it is urged that naturally a high total extraction alone should not be aimed at without paying full attention to the cost incurred in obtaining such increased extraction.

Western Coal Production

According to E. W. Parker of the U. S. Geological Survey, the production of coal in most of the Rocky Mountain States decreased in 1911 about 10%, compared with 1910. The reduction was due primarily, first, to an unusually mild winter in 1910-11; second, drought in the agricultural States west of the Mississippi river, which caused large reduction in the demand for domestic purposes in South Dakota, Nebraska, Kansas, Texas, and Colorado; third, a decreased consumption of coal in locomotives on account of the reduced traffic on practically all the Western rail-

roads; and, fourth, the resumption of coal-mining operations in the Central and Southwestern States which had been suspended during the strike of 1910. This strike in the Middle West had created an abnormal demand upon the coal mines of the Rocky Mountain States, particularly in Colorado and New Mexico. The car supply was satisfactory throughout the year, as was also the labor situation, except in the district north of Denver, in Boulder county, where a strike has been in progress since April 1, 1910. The mines of this district are being operated with non-union labor.

On the Pacific Coast conditions were not materially different in 1911 from what they were in 1910. The production of oil in California continued to be the dominating factor and probably will remain so for some years to come. The enormous production of this cheap and desirable fuel will probably have the effect of retarding the development of the Alaskan coalfields, as well as of other fields along the Pacific Coast.

Siberian Mining Outlook

Owing to lack of rain in several parts of Siberia, not only has there been a failure of crops that will result in severe famine during the coming winter, but placer-mining operations were curtailed to a considerable degree in the Lena, Nerchinsk, and upper Amur regions. While the shortage of water did not seriously affect the large producers, small-scale operators depending upon seasonal rainfall to wash alluvium were much hindered, and the lessened output of gold in aggregate is considerable.

According to recent reports from the Anadir district, which is in northeast Siberia opposite Nome, some rich placers have been worked, but on a small scale, and only by hand. Much of this work has been done by *khischniki*, Russian bar 'snipers' or 'fossickers', who have mined in territory not open to location. There have been several arrests for illegal mining, and three *khischniki* were convicted and sentenced, at Vladivostok, to one year's imprisonment. The circumstance that men will not only take the chances inevitable to mining in such inaccessible region, but will also risk imprisonment, may be taken to denote either the belief in rich placers, or perhaps is an instance of the lure of gold, particularly when occurring in distant and difficult places.

Jafet Lindeberg and his associates attempted to exploit this region under concession from the Russian Government, but through difficulties seemingly due to the terms of the concession, discontinued their work.

Mining in Western Nicaragua

The Los Angeles mine, under option to Bewick, Moreing & Co., has been returned to the owner, F. Kaufman, of Libertad. The Javali mine, I. O'Reardon, manager, is installing 9 or 10 more stamps and additional cyanide plant. The San Juan, Ignacio Suarez owner, is erecting a 22-ton capacity (leaching) cyanide plant. The Cedro mine, owned by Porter Bros., still continues in rich ore. The Costa Rica, which was to be examined by Messrs. Procter and J. M. Nicol still continues operation under the owner, as the former became ill while at Juigalpa and returned to the Pacific Coast. H. F. Lefevre, assisted by Mr. Hood, spent several weeks in the district in September, looking over properties for New York interests. The Esmeralda mine, Alfonso Hurtado owner, is producing steadily. In rank of importance the chief producing mines are Babilonia, Pedro, Esmeralda, San Juan, Costa Rica, El Carmen, Chamorro, and others.

L. VOGELSTEIN & Co. report the following figures of German consumption of foreign copper for the months of January to November, 1911: Imports of copper, 176,524 tons; exports, 8429 tons; consumption, 168,095 tons. Consumption during the same period in 1910 was 157,087 tons. Of the above quantity 155,677 tons was imported from the United States.

*From preliminary review of the year published in U. S. Geol. Surv. Press Bulletin.

Discussion

Readers of the **MINING AND SCIENTIFIC PRESS** are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

When Initial Profits Guide Wrongly

The Editor:

Sir—The greatest mistake made by many mining companies is the disbursement of big dividends when ore reserves are inadequate. Scores of companies have been ruined by such a policy, often encouraged thereto by the insistent clamors of stockholders for early profits. To pay big initial dividends, many managers have depleted their ore reserves, juggled with clean-ups, and otherwise damaged the property. It has not always been the fault of the manager—the directors demand early profits and force the hand of the manager. In other instances, unscrupulous companies have encouraged such tactics in order to promote heavy stock sales. When the company had disposed of its stock to a gullible public, the promoters retire from its affairs—leaving the shell of a once prosperous property in the hands of the new owners. This feature of the industry is one most difficult to guard against, particularly when investors happen to be of small means. The interested people, living widely apart, are not in a position to obtain any information apart from that given out by the manager—and too late they realize the deception practised upon them. The greatest safeguard appears to be the examination of the property by competent engineers, and publication of reports sufficiently comprehensive to cover completely the all-important question of future sources of revenue.

Too often have rigorously honest mining companies wrought their own ruin by the desire to disburse immense profits at an early period of their career. Such dividends could not be long maintained, and with the inevitable crash a still good mine was condemned beyond hopes of redemption, as far as the owners were concerned. Had the directorate kept a surplus on hand, and been content to disburse only fairly good profits, a complete failure would have been transformed into a profitable enterprise. One of the most striking examples of the evils attending the disbursement of early profits is the East Rand Proprietary Mines, Ltd., operating one of the largest properties in the Witwatersrand field, South Africa. This company started out with predictions of great profits, and herculean efforts were made to fulfill expectations. For a while everything went along in seeming satisfaction. Then came the news that dividends had been cut, coupled with an alleged loss of 13,462 oz. of gold. The Union of South Africa government at once appointed a Commission of Inquiry, composed largely of prominent mining engineers, and the result is now known. The necessary reduction in the dividend rate and other unfavorable features of the incident not only injured the affected company, but has doubtless reacted against others in the district. Much the same thing has happened in other fields. Not only has the erring company suffered, but other meritorious enterprises have been victims of the distrust engendered. It is one thing to lose money in a prospect where the risks are understood, but quite another to be deceived when capital is placed in a proved gold producer. In the latter it is believed the investment is sound, and such failures work incalculable harm to the industry.

In California many companies have exhausted their funds by paying premature dividends, leaving nothing with which to finance subsequent developments. The practice is less common than formerly, and most managers have adopted the wise policy of maintaining a good surplus in the treasury. Some Mother Lode companies are in a position to pay a higher dividend rate than prevails at present, but a safe reserve is added to the treasury each month. In

the history of all enterprises, mining and otherwise, comes lean periods when expenses absorb receipts and clamor wolfishly for more funds. The company having a large surplus is in a position to meet the demand, while the concern paying its entire earnings to stockholders, speedily finds itself on the rocks. The result is the closing of a property that, under more competent management, might still produce with profit. The impatience of the stockholders for large and early dividends is the principal cause of the unwise policy. Many managers realize the bad features involved, but are compelled to follow the wishes of the directors. Many engineers have resigned positions rather than carry out such plans, but there is no trouble in finding men to steer the enterprise upon the rocks. The stockholders do not realize the danger, otherwise they would be content with the receipt of lower profits and the assurance of longer life for the mine.

When the ordinary investor desires to purchase stock in a company, two prime factors command particular attention, ore reserves and management. Poor managers ruin the best mines, and a mine without reserves is simply a dent on the face of Mother Earth—neither attractive to look upon nor pleasant to contemplate. But with extensive reserves, capable, honest management, and a good surplus in the treasury, the compass points to the success that proper conditions insure.

A. H. MARTIN.

Grass Valley, California, January 12.

Professional Ethics

The Editor:

Sir—In reading the second part of the article 'Two Famous Mines,' by T. A. Rickard, in your issue of December 30, I was quite forcibly impressed by the statements relative to the purchase of the Santa Gertrudis mine by the Camp Bird company. According to Mr. Rickard, at the time of purchasing, as also before and after, Mr. Hammond was consulting engineer for the Camp Bird company and in all probability under a heavy salary. While acting in this capacity he personally obtained an option on the Santa Gertrudis property and turned it to the Camp Bird company, obtaining a large commission on the sale, an even larger commission than the regular promoter usually asks. In this region promoters are usually satisfied with 10% or less on the sale price. Asking for information, I wish to inquire if this sort of a deal is considered good ethics in the engineering profession. If Mr. Hammond was employed by the Camp Bird company as consulting engineer at a large salary, is it considered strictly legitimate for him to have charged his own company a commission that would be regarded as excessive even for an outside promoter? Is that giving the stockholders a fair and square deal? Would such a commission have been paid to any other promoter of less attainments than Mr. Hammond without comment by the stockholders? Was Mr. Hammond acting as a promoter or as consulting engineer for the company? As a mining engineer, I am simply asking for information as to the ethics of the matter.

H. C. CUTLER.

Reno, Nevada, January 4.

[The Mining and Metallurgical Society of America, of which it happens Mr. Hammond is not a member, is the only organization that has attempted to define a code of professional ethics for mining engineers. In the preliminary draft adopted by the Philadelphia and San Francisco sections of that Society, section 12 reads as follows: "It is unprofessional to accept presents, fees, commissions, or compensation of any kind from those with whom the engineer transacts business for an employer or client."—EDITOR.]

During the month of December the Elmore vacuum plant at the mines of the Sulitjelma company, Norway, produced 630 tons of copper concentrate, although this was a short month owing to holidays.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

NEVADA now contains 85 reduction plants, having 1489 stamps, including those temporarily idle. The daily capacity of plants not using stamps is 14,530 tons.

DURING the past fiscal year areas aggregating over 650,000 acres not previously examined were investigated by the engineers of the United States Geological Survey in connection with the withdrawals of water-power sites.

RUSSIA proposes to subsidize shipping at the rate of 75 rubles per ton of gross capacity and 135 rubles per indicated horse-power for steel ships constructed in Russian yards of Russian raw material. The law, if passed, is to remain in force for 15 years.

THE ATMOSPHERE is equal in weight to 1,268,000 cubic miles of water, which, however, is only $\frac{1}{250}$ of the volume of the ocean; yet this would be sufficient to raise the level of the ocean 45 ft. on all shores and to submerge an important part of the continents.

ACCORDING to estimates, the world's annual consumption of asbestos is not over 100,000 tons of all grades. Since 1877, when the Canadian industry was founded, the province of Quebec has supplied at least 75% of this, and asbestos mining is without doubt the most important mineral industry in the province.

THE BALOPTICON is an instrument that permits photographs, ore specimens, or like objects to be shown on a screen in their native colors. It is particularly valuable for use in lecture-rooms. A cheap form is available for parlor use in throwing on a screen the views on picture postal cards. For this use a smooth-surfaced card is essential.

SWEDISH iron ore now comes to America regularly. Recently the *Tellus*, a British built boat owned in Norway, brought into Philadelphia 11,600 tons of this ore for the Philadelphia & Reading Railway Co., the pioneers in its use. The *Tellus* is built of steel, 445 ft. long, 60-ft. beam, and 31½ ft. in depth. There is one 32 by 30-ft. and four 36 by 30-ft. hatchways. There are derrick hoists and 11 steam winches.

PULP from a battery, when the plates are set at proper angle and the amount of water is correct, travels down the plate in a series of waves, the lower edge of each wave rolling over and over and bringing each particle into contact with the amalgamating surface several times. The more sulphides there are in the ore, the steeper must be the slope of the plates to clear them and not interfere with subsequent concentration.

ASPIHALT is a material that passes under many names, as is well indicated by the number with which the various sorts are labeled, such as tabbyite, wiedgerite, acnite, grahamite, gilsonite, and a host of other names, which show the different varieties. There are ways of identifying these varieties, and a report recently issued by the U. S. Geological Survey contains a table showing the chief characteristics of each kind.

WATER-WHEELS, called *mangano-pygano*, are familiar objects on most Turkish farms. The common type is modeled on the Spanish *nooria*, with clumsy wooden buckets running on cogwheels, worked by horse or buffalo, the water being distributed by wood or zinc troughs, and the whole system being most primitive. Suction pumps, formed of hollowed tree trunks and fitted with piston and handle of the same material, are the common means of

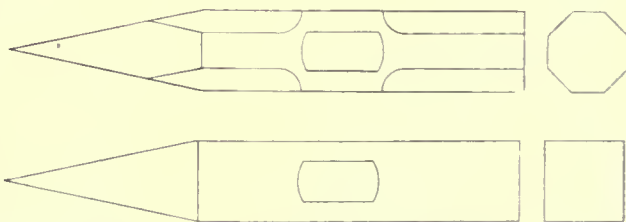

water supply of many a Turkish village; but the whole of Turkey is not so backward. On several estates mechanical pumps imported from America are at work.

ZINC-DUST is extensively used in indigo dyeing, the effect of the zinc-dust in this connection being that with milk of lime it produces hydrogen, and thereby reduces indigo blue to indigo white. The latter, being a soluble compound, is, consequently, easily absorbed by the textile fibre, and then again changed into indigo blue by atmospheric oxidation. Zinc-dust is also very extensively used for the reduction of nitrobenzol, which is the initial product of many combinations used in the production of aniline dyes. Owing to the fact that zinc precipitates the majority of ductile heavy metals from their solutions, it is often used, in the form of zinc-dust, for cleansing lyes of zinc vitriol in lithopone works, and for similar purposes.

ELECTROLYTIC apparatus and processes use or utilize the separating or decomposing power of the electric current. When an electric current is sent through a liquid material which is compound in its nature, a chemical compound, the current tends to decompose the compound into two constituents, appearing respectively at the two points of contact of the electric conducting circuit with the liquid in question, that is, at the surface or face of contact of the undecomposable conducting part of the circuit with the decomposable part. Since the current has a definite direction the constituents appear at definite electrodes. The action is simply the result of the current extracting (or tending to extract) from the electrolyte one of its constituents at each of the two electrode surfaces.

PETROLEUM was used by the Incas long before Pizarro landed in Peru at Comendador creek, where he reported the discovery of a natural spring of oil. This spring was in what is now known as the Zorritos district, in the department of Piura, province of Tumbes, northern Peru, and for generations the product was gathered in the most primitive manner by the natives. In 1864 the attention of prospectors was attracted to this district, and a small refinery was subsequently built at Tumbes; but no important development occurred in the district until 1883. Since then, however, over 300 producing wells have been sunk, and for many years these were the only fields in Peru developed to any extent. A refinery was erected at Zorritos and satisfactory refined products furnished to the home trade.

CUTTING SAMPLES in a mine is hard work under any circumstances, but must be done accurately if it is to be of value. The best tool is a moil, but when cutting overhead its use is both awkward and laborious. As a substitute, a tool such as figured below may sometimes be employed. It is essentially a moil, with an eye so that it may be mounted on a wooden handle of any con-

venient length. One man holds and guides the moil while another strikes on its head with an ordinary hammer. The point should be sharpened to accord with the character of the material to be sampled. For catching the sample cut with this tool, a candle box may be used, but, except when fine gold is present, a more convenient method is to use a canvas bag strung on an iron loop and mounted on a pole, exactly as an entomologist mounts a net for catching butterflies. This bag may be held with one hand so as to catch the cuttings, while the moil is held with the other. After each sample is cut the bag should be turned inside out and cleaned by beating or brushing.

Special Correspondence

RHODESIA

GLOBE & PHOENIX.—FOOD REGULATIONS.—COMPETITION OF BRITISH SOUTH AFRICA CO.—COAL.

A statement has just been issued by the Board of Directors of the Globe & Phoenix G. M. Co., owning the premier mine of Rhodesia, as to the position there regarding ore reserves. The statement brings the matter down to September 30 last, and in comparison with the figures published in the interim report for June 30, there is practically no change. The gross value of the tonnage standing developed in the mine today, is placed at £1,332,592, the ore blocked amounting to 177,606 tons, and this compares with 179,040 tons of an average value of 36 dwt. per ton, at the end of June last. The Globe & Phoenix is not only the largest profit earner in Rhodesia—it is, what is most important to bear in mind, the deepest mine in the country, and the fact that good widths and valuable ore are being disclosed in the lowest levels of the property, disabuses Rhodesia of a condemnation that has been often directed against it; that is, that not one really enduring ore-shoot has so far been discovered in the country.

New regulations concerning the feeding, etc., of natives in Rhodesia have just been promulgated in the *Government Gazette*. The regulations provide that natives employed both at surface and underground, on coming off night shift, shall be given one pint of hot soup, coffee, or cocoa. A minimum scale of rations (they are, 1½ lb. of meal per day, 2 lb. of beans per week, 2 lb. of meat per week, 2 lb. of vegetables, 1 lb. peanuts, and 3½ oz. salt per week) is required, and various other foodstuffs such as molasses, manioc or cassava, fruits, etc., are recommended. In regard to native huts, it is required that air space per head shall not be less than 250 cu. ft., and that no hut shall have a lesser height than 8 ft., measuring from the centre of the floor to the apex of the roof. Under the new regulations there will have to be 15 ft. between each hut, reckoning from eaves to eaves. These regulations are typical of the endeavors now being made all over South Africa to better the lot of the native workers at the mines, to lower native sickness and death rates, and generally to improve the efficiency of the unskilled laborers. Similar motives induced the Transvaal Chamber of Mines to engage the services of Sir Almroth Wright, the eminent English bacteriologist, to investigate the causes of, and remedy for pneumonia on the Rand, and if possible to discover a vaccine for a disease which yearly carries off hundreds and hundreds of valuable mine laborers, especially those hailing from tropical and sub-tropical areas. The Rhodesian mining authorities have been endeavoring to secure the co-operation of the Chartered Company Government, with a view to obtaining the services of Sir Almroth Wright for Rhodesia, as well as the Rand. The Government, however, has taken the attitude that Rhodesia, in common with the rest of the world, will benefit by Sir Almroth's Transvaal researches, and that in consequence the Government does not see fit to go to the expense of engaging the eminent scientist specially for Rhodesia. To this, the Rhodesia Chamber of Mines replies that conditions in Matabeleland and Mashonaland are vastly different to those obtaining in the southern Transvaal, and urges the Government to reconsider its decision in the matter.

The Rhodesia Chamber of Mines, like similar institutions in other countries, seldom appears to find its members in fairly complete agreement with the Government on any particularly important new laws or new policy. The action of the British South Africa Co., in floating a Mines Development Co., to promote mining, assist prospecting, and form subsidiary companies, has drawn forth a loud cry of protest from the larger and more important mining corporations operating in the country. The mining corporations urge that the flotation, under Government auspices, of such a concern should be postponed until the administrative and commercial departments of the British

South Africa Co. are more clearly divorced, than at present. They also point out that the British South Africa Co.'s venture will be in a position to compete, under exceptionally favorable terms, with companies floated in Europe on European capital. Apparently, the Chartered company's latest flotation scheme, while it may be considered good business by the 'small man' mining element, is not looked upon with grave concern by the large and influential limited liability companies.

Much importance attaches itself to the exploitation of coalfields in Mashonaland by the Consolidated Gold Fields of South Africa. Hitherto the only working colliery in southern Rhodesia has been at Wankie, in northern Matabeleland. The more important gold-belts are situated at a considerable distance from the Wankie pit, and in consequence the cost of transport on fuel has been very large; in fact, to many mines it has been prohibitive, and wood has been consumed. Especially have the properties most distant from Wankie, that is, mines situated in eastern Mashonaland, suffered. The area selected by the Consolidated Gold Fields company is situated about 75 miles west

TYPICAL SMALL MINE IN RHODESIA.

of Gatooma, and in extent amounts to 200 square miles. Work has been proceeding there for about six months, and the latest reports received from the property are highly encouraging.

LONDON

CLAIMS OF THE TANGANYIKA CONCESSIONS.

A few weeks ago I wrote about the present position of the Tanganyika Concessions, the great organization controlling the copper deposits of Katanga, in Congo Territory, in the very centre of Africa. The venture has been strongly criticized in this country, in your pages, and in other publications from America. Of the latter I may mention particularly the comments in Stevens' 'Copper Handbook.' Mr. Stevens, while admitting the existence of wonderful deposits, postpones their profitability for a century or two, on account of the difficulties of metallurgical treatment and the lack of transport. It is a rather exaggerated view, but is based on sound enough sense. There are, however, many shrewd men of fine character in this country who have faith in the deposit and in the capability of Robert Williams, the man at the head of affairs. Moved by their urgent pleadings, I am inclined to give some space this week to an outline of the statement made by Mr. Williams to the shareholders. The property is in Congo near the Rhodesian border, and the ownership and control is divided between the Belgian company, the Société Minière de Haut Katanga, and the English company, the Tanganyika Concessions. In addition, there are many affiliated companies engaged in mining and railway construction, the exact relation between all in the group being too complicated for description here. The adverse critics have made much of the scarcity of instructive detail and the disinclination of the controllers to engage experts of the highest standing. One of their strongest arguments

was that R. J. Freeheville's clients never took any financial interest after he had carefully examined the deposit and presented an elaborate report. Nor was the nature of the report ever divulged. This leads me to the most interesting of all the statements made at the recent meeting, a remark, really quite incidental, to the effect that Mr. Freeheville had vouched for 1,800,000 tons of 12% ore. This publication of his view has greatly cleared the air, and it is now permissible to presume that it was the want of communications with the outside that made him cautious in recommending his clients to invest their capital. He evidently felt that conditions, though ultimately promising, would be worse before they were better. Therefore the shares would be in danger of assessment; and in any case, were offered at too high a price. For a finance company that does not care for an undetermined lock-up, the speculation was not entirely inviting. Another interesting announcement related to the cost of coke. No African fuel was available, either as to quality or cost, when smelting was first contemplated, so it was decided to take the bold course of importing coke from Europe. A few months' experience has shown that this coke has cost £12 delivered, and that much more has been used per ton of copper produced than was originally announced, owing to the necessity of adding fluxes to the aluminous ore. Smelting started at the end of last June with one furnace, and after several trial runs, a continuous run was made of nine weeks, from the middle of September to November 20. During this time 1000 tons of copper was produced, and the recovery was 87% of the content. The operations were successful and a second furnace is being built. As regards the coke question, recent negotiations have provided for the supply of coke made at Wankie colliery in Rhodesia to be delivered at £5 per ton. The fuel outlook has also been improved by the discovery of good coking coal in Luano valley, a deposit under the control of the Tanganyika Concessions. It is possible to mix some charcoal with the charge, and as this costs less than £2 per ton the reduction in cost thereby effected is appreciable. Mr. Williams was not quite so convincing when he referred to the nature of the ore deposit, for he still trusts that sulphides will be found in depth. Those who have been on the spot or who have seen the ore are inclined to the view that the deposit is shallow, and has not been derived from ascending waters of igneous origin, but has been formed from the erosion, solution, and transport of earlier deposits elsewhere. As regards the railway position, good progress is being made with the Benguela railway to Lobito Bay on the west coast of Africa. When completed this road will work wonders in the development of Central Africa, for it will bring it into much closer connection with Europe. For the past year or so the Katanga district has been connected with the Rhodesian railways, thus permitting through communication to Cape Town or Beira; but of course these lines are in the wrong direction and their rates are appalling. I have given the above outline of the present position in a spirit friendly to the enterprise. I trust your readers will understand my motive, as I do not withdraw anything that I have written previously.

SILVERTON, COLORADO

NEW ZINC SEPARATOR AT SUNNYSIDE.—CYANIDE PLANT FOR GOLD BUG.—IOWA TIGER DEVELOPING.—SILVER LAKE INCREASES FORCE.—HERCULES AGAIN IDLE.—SILVER LEDGE CHANGES MANAGEMENT.—CONGRESS DEVELOPING.—AGITATION FOR CYANIDE PLANTS.

The new zinc separator plant at the Sunnyside mill is nearing completion and will probably be in operation within the next 60 days. The Gold King lessees made a mill-run during December with excellent results. The mine will be developed during the winter by sub-lessees, and a large tonnage will be available for the mill next summer. It is reported that the Gold Bug M. Co. has ordered a 50-ton cyanide mill for the Gold Bug mine, and that the machinery is now in transit and will be erected this spring. The Intersection is hauling supplies for an

increase of five stamps in its battery capacity, and the new battery will be set up and ready for operation during the spring. The Iowa Tiger mill was run for several days in December, and the lessees shipped six cars of concentrate. A force of 25 men is employed on development, but no new orebodies have been discovered. The Silver Lake has increased its force at mine and mill and is now operating two shifts and milling more than 100 tons per day. The force will be increased to three shifts when the Durango smelter is again blown in. The Hercules is again idle, and Mr. Kane, the manager, is East in conference with the stockholders as to future operations. The Silver Ledge mine and mill are operating at full capacity and producing two cars of concentrate per day. W. Z. Kinney has resigned as manager, and the mine is now under the control of Karl Knupfer, secretary, pending the arrival of Mr. Arnold, recently in charge of the Casa Diablo mine, California, who has accepted the position of manager for the Ledge. The mine is making a very favorable showing at present and seems in position to become a steady producer. The Southern E. & M. Co. is developing the Congress mine and expects to ship this year. An ample supply of coal and all necessities of life are now on hand, and the railroad has reduced its train service to normal. There is a good deal of agitation at present for cyanide plants, and it is probable that several will be erected during the coming season. Much of the agitation has been carried on by men inexperienced and poorly informed in the art of cyanidation, and many failures and much discouragement will no doubt result. These can, of course, be avoided by the enlistment of expert advice as to the adaptation of cyanidation to San Juan ores and proper methods of procedure in each case. The danger lies in proceeding without such help and in thinking that cyanidation is a simple panacea for all the metallurgical troubles of this district.

GOLDFIELD, NEVADA

CONSOLIDATED MINES CO. SHIPPING TO DENVER MINT.—ROASTING PLANT ABOUT FINISHED.—FIELD NOTES OF THE DISTRICT.

The Consolidated Mines Co. now ships all its bullion to the U. S. Mint at Denver, instead of to the Selby company at San Francisco, as formerly. The latest shipment was valued at about \$220,000. The company's new roasting plant, designed for the final treatment of residue from the present concentrate-treatment plant, is practically completed. It has cost the company about \$72,000 and is expected to effect a saving of at least \$80,000 per year. Lateral development is now in progress from the Grizzly Bear shaft at a depth of 1300 ft., this being the deepest shaft in the Goldfield district. It is near the Clermont shaft, which is nearly 1100 ft. deep. The Hazel shaft, on the Miss Jessie claim of the Laguna group, has been sunk to nearly 900 ft. and from this point a cross-cut is being driven to a point under the main Laguna shaft, which will be sunk to greater depth and will be the main point from which the Red Top vein will be explored.

On the Florence Goldfield property development continues on the lines planned prior to the destruction of the company's mill. Lateral work is in progress on the 350, 530, and 650-ft. levels, and the shaft is nearing a depth of 1000 ft. At this depth a sump will be sunk 60 ft., and drifts and cross-cuts will be started in the direction of the veins that have produced on upper levels. Lessees have begun work on the Gold Coin claim of the Jumbo Extension, in the Diamondfield part of the district, and adjoining the Goldfield Daisy. Six leases in all are now working on the claims of the C. O. D. Consolidated, and are, for the greater part, exploring virgin ground, extending to the boundary of the Atlanta. An important announcement, involving the early development of the Atlanta on a large scale and at great depth, is expected soon. It is announced by officials of the Silver Pick Consolidated that active development will begin on the company's claims during the present month and that a working shaft

will be sunk to great depth at a point 250 ft. distant from the boundaries of the Combination and Mohawk claims of the Consolidated.

In the Diamondfield part of the district seams of high-grade ore have lately been found by lessees on the Black Butte, near the 100-ft. level, and this shaft will be unwatered and a drift will be driven on the vein at greater depth.

On the Goldfield Belmont the rich ore-shoot exposed on the 300-ft. level and later followed a long distance in a drift from the winze on the 350-ft. level, is said to have been followed to a point near the boundary line of the Daisy, and miners believe the ore-shoots of this large vein pitch to the south, toward the latter property. The Belmont has produced some rich ore recently, and the winze will at once be sunk another level.

Old workings of the Daisy mine are being cleaned out and repaired in preparation for development at the hands of the Daisy-Belmont Ledge company, which has acquired a long-term lease on the greater part of Daisy territory and will proceed to explore for the southern extension of the Belmont vein. It is the plan of F. A. de Costa, manager for the company, to sink the main or No. 2 shaft, now down 530 ft., to penetrate the Belmont vein, which, according to the dip indicated on upper levels, it should cut at about 700 feet.

NEW YORK

EQUITABLE FIRE.—RIVAL INTERESTS JOINED IN INSPIRATION CONSOLIDATED.—UNITED VERDE EXTENSION REORGANIZATION.—GENERAL MARKET NOTES.

New York has stood this week to watch the destruction of one of the most important of its monuments in the financial district. Fire destroyed the old fashioned eight-story Equitable building, originally built by the elder Hyde, the founder of the Equitable Life Assurance Society, at an expense of some eighteen million dollars. It was the first structure in New York to be equipped with passenger elevators. It contained the offices of the Harriman roads, the Union Pacific and the Southern Pacific, and its safe deposit vaults were the most important in the city. Many securities were lodged in the vaults, which were so covered by piles of debris and many feet of ice that not until the afternoon of the third day were they partly uncovered. In the meantime the regular deliveries on the New York Stock Exchange were temporarily suspended and the various banks which were housed in the burned building and in the adjacent structures were obliged to open temporary offices wherever accommodations could be found. Market operations were therefore much interrupted.

Perhaps the most significant development of the week in mining affairs is the formation of the board of directors of the new Inspiration Con. Copper Co. The members of the new board include some of the most important figures in the financial world and bring together some interests which have for many months been looked upon as antagonistic. A study of the various names and the connections of the individuals is worth while, distinctly so, in view of the much discussed copper merger. With the world's greatest industrial combinations, either in the throes of dissolution, or under fire of investigation, the banking interests have hesitated to apply the trust principle to copper. From the roster of the board of directors under discussion it might be suspected that the activity of the Federal authorities and the uncomfortable features of the Sherman anti-trust law are to be evaded and avoided, or at least circumvented, by the older device of co-operation and community of interests.

The president of the newly consolidated company is William B. Thompson, a special partner in the house of Thompson, Towle & Co., of New York and Boston. Mr. Thompson is interested in many mining ventures, among them Nevada Consolidated. Mr. Thompson was one of the original promoters of the old Cumberland Ely Copper Co., which was merged with the Nevada Consolidated; the Mason

Valley, at Yerington, Nevada, which has recently entered the producing ranks; and others.

The vice-president is William D. Thornton, president of the Greene Consolidated Copper Co. The connection with the Cole-Ryan is close and complete, as both Thomas F. Cole and John D. Ryan are directors, and the Standard Oil, Amalgamated connection is further evidenced by the name of William G. Rockefeller. The names which carry a peculiar significance by their presence are those of E. C. Converse, president of the Bankers Trust Co., a Morgan institution, and by reason of recent absorptions of other banking houses, the most important trust company in New York, and that of Eugene Meyer Jr. Eugene Meyer, Jr. & Co. is looked upon as a distinctly Morgan factor, and has always been credited with being the connecting link between J. P. Morgan & Co. and the Guggenheims. The joining of these names in this way may or may not carry any particular meaning, but in view of the recent action of the copper metal market and the very evident strength of the pools behind the recent upward movement, it certainly justifies the inquiry as to whether the two recognized leading factors in the production, refining, and marketing of copper have abandoned all idea of competition and whether the copper merger may not become a reality in this form, so tangible for all working purposes, but impalpable as to any outside attack. To be sure, the Inspiration-Live Oak properties are not in themselves of any overwhelming importance, but the bringing together around the directors' table of the various banking interests described is important and future moves in the like direction will be intently watched.

Other members of the Inspiration board are W. E. Corey, former head of the U. S. Steel Corporation; Philip L. Foster, of the London Exploration Co.; and Henry B. Hoyland, who represents the Live Oak people and who primarily is affiliated with people of the Lake Michigan copper country.

A reorganization of the United Verde Extension is being planned and the stockholders are informed that some important mining interests are to be brought into the company, under an agreement, by which the present company sells 25,000 shares of its present treasury reserve to the new investors coming in, at \$1 per share, which purchaser shall then have the right to form a new company and in exchange for two-fifths of the stock of the new company shall receive all the property of the present corporation. A like amount is to go to the purchaser in consideration of \$200,000 to be placed in the treasury of the proposed company, which shall also receive the balance of one-fifth of the stock. It is reported, and denied, that the "important mining interest" referred to is the Phelps-Dodge company. The camp of Jerome is something of an anomaly. W. A. Clark has drawn enormous revenue from the United Verde for many years and has been singularly fortunate in having no strong encroaching neighbors, such as have made so many stormy chapters in the history of Butte, Montana. There are several developments adjacent to the United Verde besides the United Verde Extension. The Hull Copper M. Co. and the Cleopatra Copper M. Co. are both said to have prospects of some promise, but are each capitalized for some ten millions of dollars and without efficient management, so that Mr. Clark has been able to build his mansion in Fifth avenue, New York, for the delight of the strollers in the avenue and park opposite without fear of anything worse happening at the mines than the caving under the old smelter. The entrance into Jerome of any such powerful factor in copper as the Phelps-Dodge company would undoubtedly start Mr. Clark to building a fence at home, a labor which he has so far been spared in Arizona, though his experience in Montana made him one of the most far famed of expert fence builders. The Clark campaigns in Montana are history—most exceedingly interesting history when one can lure some ex-member of the Montana legislature of those days into a reminiscent mood.

The report of the Copper Producers' Association shows a steady improvement in the copper situation, and 15c. copper is looked upon as an assured fact. There still remains

some skepticism as to the real foundation for the boom in copper; it is pointed out that there has been no marked revival of business at home, in fact, domestic deliveries decreased in December something over 2,000,000 lb., production increased some 11,000,000 lb., while exports ran up some 12,000,000 lb. over the preceding month, reaching a total of 79,238,716 lb., breaking all records for foreign deliveries for any one month since the Producers' Association was formed. According to the association's figures the accumulated stock of copper in this country is smaller than at any time within the past three years, having been cut down in the past eighteen months from a high mark of 168,276,017 lb. in July 1910 to 89,454,695 lb. on January 1, 1912. During the same period the world's visible supply has decreased from 401,139,697 lb. to 217,768,615 lb. It is idle to speculate as to the genuineness of the rise in copper metal. The situation has not been a healthy one, foreign manufacturers seemed destined to accumulate large profits from cheap copper furnished by mines in this country, while domestic consumers could neither buy for future use with prudence nor otherwise take advantage of the low prices prevailing. One thing is certain—producers, smelters, refiners, and selling agents are getting closer together, and undoubtedly it will not be long before prices are maintained, if, indeed, the present level cannot be held without undue reaction.

The Nevada-Utah reorganization has developed into something of a scrimmage for the support of the stockholders by various committees. Theodore Gross, of the Hirsch Syndicate and long identified with the Venture Corporation of London, is working with the present officers of the company to float a bond issue with the shareholders. In any event it is quite certain that further complications will be added to the organization, which is already involved past any reasonable comprehension. There may be those in the company who understand or claim to understand thoroughly the corporate organization of Nevada-Utah, but to prove such understanding would take a long time and much argument. There are now some ten thousand shareholders, who are asking whether they shall or shall not throw good money after bad, and so long as they will donate sums small or large, there will not be any great difficulty in finding reorganization committees to administer the funds so collected.

BLACK HILLS, SOUTH DAKOTA

STATE CONDUCTS PROSPECTORS' SCHOOL.—WINTER UNUSUALLY SEVERE.—WASP NO. 2 PRODUCTION.—DEADWOOD ASSAY OFFICE BREAKS RECORD.—NEW DEVELOPMENT.

For the benefit of men who cannot attend a full year, the South Dakota State School of Mines, at Rapid City, is this winter giving a short course in mining and metallurgy. The classes began on January 4 and will continue for six weeks.

The Black Hills has been experiencing an unusually severe winter, and train service has been maintained only by heroic work. The mills depending upon railroad haulage of ore from mine to mill have been hampered somewhat by delayed trains, and outside work has been almost entirely suspended. Construction work has been suspended at one or two properties, and work at the Wasp No. 2, where the ore is mined in an open cut, has been entirely suspended until better weather comes. This step was finally decided upon after strenuous efforts had been made for a number of weeks to keep the operations up to normal. This proved too expensive, and it was decided to suspend until the weather gets warmer. During the year 1911 the Wasp No. 2 produced \$286,000 and paid \$60,000 in dividends, while other profits of operation were devoted to liquidating indebtedness incurred during the construction of the new mill, which plant was built in 1910 to replace one destroyed by fire early in that year.

During the quarter ended December 31 the United States Assay Office at Deadwood purchased South Dakota bullion to the value of \$2,042,000, which was the largest quarter's business in the history of the office.

In 1911 three new gold producers of substantial size

were added to the Black Hills list. These were the Castle Creek dredge, and the Trojan and New Reliance cyanide mills. The Richmond-Sitting Bull mine, at Galena, was reopened during the year, and steady shipments of silver-lead ore were made to smelters. Among the new producers which will start during the present year are the Black Hills smelter at Galena, the Evans Consolidated in Spruce gulch, and the Bismarck Consolidated at Flatiron, adjoining the Wasp No. 2. The smelter people are interested in mines at Galena and Two Bit, and the plant will offer a market for the product of a number of mines which are preparing to commence shipments when the plant is ready for ore. The Bismarck Consolidated is constructing a dry-crushing cyanide plant which will have a capacity of 300 tons per day. The cold weather has seriously interfered with construction work, but it is expected that the plant will be ready for operation early in the spring. The Evans Consolidated is repairing the Lexington Hill 20-stamp cyanide plant, in Spruce gulch, near Deadwood.

Wood Brothers, of Montreal, have secured an option on the bonds of the Hidden Fortune and Columbus companies, at favorable terms, and are having a thorough examination made of the property of the companies. There are two shafts, one 300 and the other 500 ft. deep, to be unwatered, and a large amount of other workings to be sampled. It is estimated that this work will cost in the neighborhood of \$25,000. It will be started at once. Should the results prove satisfactory, a company will be incorporated to take over the property of both companies and work undertaken on a scale second only in importance to the Homestake.

Eastern investors are interested in the Kicking Horse and Carrol ground, in Blacktail gulch. This property is known to contain a large amount of medium-grade ore, which could be handled by cyaniding, and the new company plans erecting a plant at the property. Articles of incorporation of the company are being filed in Illinois. The moving spirit of the enterprise is Fred G. Jones, of Chicago.

The Golden Reward company is shipping ore to its mill from the Wells Fargo ground, in Blacktail gulch, after allowing the property to lie idle for a number of years.

The Iron Creek Placer G. M. Co. is to start, early in the spring, hydraulic mining on Iron creek, in western Lawrence county. The company secured nearly two miles of the creek. E. Bright, of Columbus, Ohio, and associates are financing the company.

Boston capitalists have purchased the Gladiator ground, in upper Deadwood gulch, from the owner, Burt Rogers, of Deadwood, and have made a substantial first payment on the purchase price.

The Gold King M. Co. has been incorporated, as a subsidiary of R. Bunce's Black Hills Development & Financial Corporation. The capital of the Gold King is \$500,000, in shares of \$1 each. Of this amount the B. H. D. & F. corporation proposes to retain 251,000 shares, and to offer the rest to the public. The company will undertake the development of the Gordelia property, near Rockford, which is equipped with a mill. It is proposed to equip the mill with a cyanide department.

O. N. Brown, of Deadwood, is working on plans for transporting ore from the Victoria Extension property to the Victoria mill, a distance of about a mile and a half. It is proposed to construct a tramway around the hill, over which the ore will be hauled to the loading terminal of the aerial tram at the Victoria mine, and thence taken to the mill. During the past few months the Victoria Extension has been opened up in good shape under A. J. Malterner, general manager, and a large amount of ore is blocked out ready for treatment. The Victoria owns a first-class dry-crushing cyanide plant.

Cantfield & McLeod, of Hill City, owners of the Golden Summit mine, near that place, are developing a rich ore-shoot, and as soon as the weather permits of easy working, will start the mill. Many other companies will be glad of the advent of warmer weather, as the winter time is especially disadvantageous for new construction.

General Mining News

ALASKA

KETCHIKAN

A 12-ft. vein of copper ore has been discovered on the Redwing property, of which R. W. Dwyer is superintendent. Richard Nuckles recently found rich gold ore while doing assessment work on the Goo Goo group on Thorne Arm, near Sea Level, says a newspaper report.

PRINCE WILLIAM SOUND

The adit on the Errieson copper property, on Glacier creek, has been driven more than 60 ft. and is in high-grade ore. Mr. Errieson is mining blacksmith coal a few miles from Glacier creek. The copper property is financed by an English company.

ARIZONA

COCHISE COUNTY

The Phelps-Dodge Mercantile Co. has been incorporated to take over the mercantile interests of the Copper Queen, Detroit Copper, and the Southwestern mining companies, the last having its property at Dawson, New Mexico. The headquarters of the new company, which is capitalized at \$4,000,000, will be at Bisbee.

The Calumet & Arizona M. Co. has accepted plans for its new smelter, state recent newspaper reports, and construction will start in the immediate future. The plant is to be completed in eighteen months, and will cost nearly \$2,000,000. It will be built at Douglas.

GILA COUNTY

It is reported that the Duquesne M. Co. has started shipping ore to the El Paso smelter. J. F. Shaw is manager for the company. T. C. Hendricks, president of the Douglas Copper Co., owning 25 claims in the Kay district, says a report from Miami, is about to go East to purchase a churn-drill. The Gibson Copper Co. has resumed work at the Gibson, formerly under option to the Summit Copper Co. T. Henderson is superintendent. It is rumored that A. A. McKinsey has sold his five claims adjoining the Live Oak property to the Inspiration Consolidated.

The Miami Copper Co. continues to produce at the rate of 2,500,000 lb. of copper per month from the milling of 2500 tons of ore per day. The Hardinge mills for the sixth unit have been shipped, and this unit should be in operation by February 1. The third 1200-kw. generator set has been erected in the power-house, and the installation of the duplicate Nordberg compressor is well advanced.

MOHAVE COUNTY

Press despatches state that the mines of the county during 1911 produced \$2,052,071. Of this, the Gold Road Mines Co., a subsidiary of the United States S. R. & M. Co., produced in its nine months of life, \$673,540 in gold and silver, and the Tom Reed mine \$747,680 in bullion.

CALIFORNIA

AMADOR COUNTY

It is rumored that the Central Eureka mill will resume operation in the near future on ore from the 2700-ft. level of the company's mine.

BUTTE COUNTY

Newspaper despatches state that a new dredging company has been organized at Chico to operate a dredge below Oroville, on the Feather river.

KERN COUNTY

Reports from Randsburg state that the new hoist of the Good Hope mine, owned by the Consolidated Mines company, has been erected. The mine has 50 tons of ore ready for milling.

Ed Cook and Ernest Peden have secured a lease on the Magpie claim of the King Solomon property. James Rice, a lessee on the same property, has found good ore at a depth of 100 ft. The International Mfg. & M. Co. has moved its dry washer to the Baltic placer property. George

W. Cordon, of Portland, Oregon, a director of the company, is supervising a demonstration of the washer. T. W. Pack and associates, of New York and Los Angeles, have a force of men at work on the property claimed by the California Trona Co. at Borax lake. W. A. Austin, receiver for the property, has warned them off, but no action has been brought in court. J. G. White & Co., of San Francisco, have purchased from the National Tube Co. 124 miles of 12-in. steel pipe for a natural-gas line for the Midway Gas Company.

MONOC COUNTY

Renewed interest is reported in the High Grade district, a few miles from both Oregon and Nevada. The shipping point for the district now is New Pine Creek, on the N. C. & O. railroad, eight miles distant. An 8-in. vein of ore assaying about \$1000 per ton is reported to have been found on the Sunshine property at High Grade.

SIERRA COUNTY

A large shipment of machinery for the Sierra M. Co.'s plant at Pike City, which is being rebuilt, is now at

CALIFORNIA, BY COUNTIES.

Nevada City. It is reported that probably the machinery cannot be delivered this winter. George St. John, superintendent for the company, has returned from an Eastern trip.

SISKIYOU COUNTY

Joseph Detto, who has a lease on a placer mine owned by George Simmons, recently discovered valuable ore at bedrock. The deposit is over a foot in depth, and the width has not been ascertained. The property is near Hawkinsville.

TUOLUMNE COUNTY

(Special Correspondence.)—Rich ore has been uncovered in the south drift on the 1100-ft. level of the Harvard mine, which is situated near Jamestown. The quartz exposed is flecked with gold. The Harvard has been operated continuously during the past several years, employing at times as many as 125 men. It was a heavy producer in the early days when it was known as the Whiskey Hill mine.

A few men are working at the Gold Crater, in the Knights Creek district, and in a short time active operations will be resumed. A Burleigh drill has been purchased.

Development since the finding of the new orebody on

the 400-ft. level in the Providence supports the belief that the shoot is large as well as rich. The rock contains considerable free gold. The work of cleaning out and retimbering the shaft, which had progressed to a point below the fourth station when the crew was removed to do some development work, is about to be resumed.

Articles of incorporation of the Long Gulch Mining & Development Co., organized under the laws of California, have been filed in this county. The capital stock is \$250,000. The directors are Thomas G. Winwood and Andy Matijawich of Oakland and Ernest Harrison, J. J. Morrisey, and A. C. Broadfield of San Francisco.

Tuolumne, January 13.

VENTURA COUNTY

(Special Correspondence).—The National Borax Co. is planning to purchase motor trucks to transport its product from the mine, near Stauffer, to Bakersfield, in Kern county. The distance is about 60 miles. A 2-compartment shaft is to be sunk in the near future. The property at present is developed on four levels. The company, which is capitalized at \$1,000,000, acquired its property from the United States Borax Co., and has a calciner at the mine and a refinery in Jersey City, New Jersey. About 5000 tons of material is ready for transportation, it is reported. The property has not been operated for four years, but was well developed before then. The new company will start operating within 45 days, according to a recent announcement. Max P. Fries of Los Angeles is president of the company. Stauffer, January 14.

YUBA COUNTY

The property of the Northern California Gold Mines Co. is to be sold at private sale, January 20, at the office of Richard Belcher, referee in bankruptcy, at Marysville.

C. H. Campbell, owner of the Branborough mine at Browns Valley, has found a vein of rich ore, believed to be a continuation of the old Pennsylvania. He has sunk a shaft about 20 ft. from the first drill-hole with encouraging results.

COLORADO

CLEAR CREEK COUNTY

Tentative development will be started soon at the Pulaski mine, which has not been operated for several years. B. F. Kelly will have charge of the work. If a test shipment of a carload of ore gives satisfactory returns, a compressor and mill will be erected, and development started through the Hall adit. George Bergen and Jeff Richards, lessees on the Sunset property, Covode mountain, recently discovered ore assaying more than \$20 per ton in gold.

DOLORES COUNTY

The Rico M. Co. is planning to lease the Phoenix, Nigger Baby group, Laura, Power House, Golden Age, and other properties on Newman hill, states a recent newspaper despatch, as the company's holdings cover too much ground to permit adequate exploration in any reasonable length of time. The company reserves for its own development the Shamrock mine and some of the property on the southeastern part of Newman hill, south of the Group adit.

OURAY COUNTY

The annual meeting of the Gold Trio Mines Co. was held January 5 at Ouray. The company's holdings include the Grizzly Bear group, the Nordica group, a one-third interest in the Senator Beek group, and other properties. The Grizzly Bear group, the principal property of the company, is stated to have about 3000 ft. of development, all in ore, and during the summer of 1911 a number of cross-cuts were driven, proving the orebodies extend from end to end of the property. The past production of the group is given at \$335,700. More than 100,000 tons of broken ore is stored. No. 5 level has 15,200 tons of ore averaging about \$10 per ton, it is claimed. Samples from the Nordica, it is asserted, have assayed in high figures. Paul J. Simones, as president of the company, heads the list of officers elected at the meeting.

The Arps-Krisher M. Co. is reported to be planning an adit under the Pony Express contact from the Lenore

side. Its last ear averaged close to 400 oz. silver per ton.

TELLER COUNTY (CRIPPLE CREEK)

To provide water for the Argall mill, the first low-grade plant of its kind in the State, the Golden Cycle, Vindicator, and Independence companies have combined to unwater the Cycle shaft, which has filled to the 1100-ft. level. The Argall mill has been closed for some time, as its usual water-supply, from springs, has been frozen. The agreement was announced by Joe Carr, superintendent for the Golden Cycle company.

The Mable M. Co., operating on Beacon hill, in December produced 1186 tons of ore averaging over \$17 per ton. Receipts from royalties and the sale of its own ore amounted to about \$6000. Shaft-sinking has been stopped for the present owing to water.

The Blue Bird, E. S. Johnson manager, is working with a full force of 40 men. The old employees were not taken back, owing to their objection to the discharge of a foreman.

Three shifts are developing the lower levels of the W. P. H. mine, Ironclad hill. Oscar Fogleman has a lease on the property.

J. B. Giroux, lessee in the Deadwood mine, Bull hill, has opened a shoot of ore from which grab samples assayed \$120 per ton.

It is reported that the Jerry Johnson mill may be put in operation. A recent decision of the district court awarded title to it to Edwin Gaylord. The mill uses the cyanide process.

The annual meeting of the Elkton Con. M. & M. Co. will be held February 12 at Colorado Springs.

IDAHO

LEMMING COUNTY

Newspaper despatches state that an independent company will drive an adit from the town of Gilmore to meet the Allie M. Co. and Pittsburg-Idaho company's mines at the 500-ft. levels. A spur track will be built from the railroad to the portal of the adit so that ore can be delivered from the mines to the bins or cars direct. It is estimated that the adit will cost about \$75,000 and will require nine months for construction. It is believed that the economy it will afford in transportation will mean a saving of nearly \$100,000 per year. A. S. Ross, president of the Pittsburg-Idaho company, and Maurice M. Johnson, consulting engineer to the same company, head the party which will select the route. Prominent mining investors of the district are said to be interested in the proposed company.

SHOSHONE COUNTY

The Amazon Development Co., Ltd., has been organized under the laws of South Dakota to take over the Amazon-Manhattan property on Sunset peak. General offices will be at Galesburg, Illinois, and the mine office at Wallace. C. C. Barth will be in charge of the property.

According to recent reports, the Tuseumbia mine has been purchased by Butte capitalists, who will increase the capitalization of the company to \$1,000,000. A mill may be erected in the spring. The main office will remain at Wallace, although a branch office will be established at Butte.

The Mammoth mill has been shut down, owing to the lack of water, and it is rumored that several other mills may be closed for the same reason. There has been less water this season than for the past 13 years. The lack of water is caused by the continued cold.

The Bunker Hill & Sullivan M. & C. Co. last week paid dividend No. 172, making a disbursement of \$65,400. The total in dividends paid is now \$13,225,050.

The Success M. Co. has paid a dividend of \$15,000, making the total disbursements for the past six months \$45,000. The output of the mine is being steadily increased and sinking commenced from the lower adit.

MONTANA

LINCOLN COUNTY

(Special Correspondence).—John H. Town, principal

owner of the Shaughnessy hill mining property, has resumed operation there with a double shift. The lower adit will be driven to cross-cut the vein at a depth of 300 ft. This adit is now in 500 ft. and it is thought that the ore will be reached within thirty days. In the upper adit, which intersects the vein at a depth of 145 ft., there is a good showing of silver-lead ore, much of which is rich enough to ship without concentration.

Libby, January 16.

SILVERBOW COUNTY

A stockholders' meeting of the Butte Coalition M. Co. will be held January 20 in Jersey City, New Jersey, to consider dissolving the company.

NEVADA

CLARK COUNTY

Theodore Park and William Kerwin recently discovered a 10-ft. vein, four feet of which assays about \$100 pre ton, in the Chiquita district, adjoining the Chiquita mine, states a report from Searchlight. Development is active in the Lost Basin district, just south of the Chiquita district.

During 1911 Clark county mines produced 11,317 tons of ore, valued at \$66,723, according to recent newspaper estimates.

It is reported that a stamp-mill is to be erected at the Crystal Ledge property, near Barnwell. The mine is owned by Mrs. C. E. Barringer, formerly a hotel manager of Searchlight. There is 115 tons of ore ready for milling.

ELKO COUNTY

Ed Benane and Thomas Beadle have secured an option on the Alphas property near Jarbidge.

ESMERALDA COUNTY

The Daisy-Belmont Ledge M. Co. in the near future will sink the No. 1 shaft on the Goldfield Daisy property to a depth of 300 ft. where connection with the No. 2 workings will be made. Other development of the property also will be started to tap the Belmont vein.

To permit commercial tests of the coal in the recently developed fields at Coaldale, mentioned in this department in previous issues, the Tonopah & Goldfield railroad recently distributed gratis a carload shipped from the Nevada Coal & Fuel Co.'s property.

One item included in the Goldfield Con. company's December preliminary report, already published, was \$42,000 expended for new construction. Development is making normal progress, and it is said that ore of excellent grade has been exposed in new workings. The new roasting-plant, designed to treat the residue from the present concentrate-treatment process, is practically completed, at a cost of \$72,000, and it is expected to effect a saving of at least \$80,000 per year.

The work of enlarging the St. Ives shaft, 480 ft. deep, of the Goldfield Merger Mines Co. has been completed, and sinking is in progress. This stage has been reached earlier than was anticipated. The shaft is now of three compartments, with the timbers so framed that those for the fourth can be adjusted readily. The compartments are 4½ by 5 ft. in the clear. Timbers are 10 by 10 in. from surface to the water-line, and below this point are 12 by 12 inches.

HUMBOLDT COUNTY

A new crew of men has been engaged at the Mayflower National main workings, and sinking on the vein has been started. It is reported that last month's production of the National mine was valued at more than \$189,000. E. M. Stewart and Frank Christenson are developing the Platona group, near Rebel Creek. The claims formerly owned by M. Atkinson and W. Trengoe, near National, reputed to be unusually rich, were re-located January 1 by Stanley Chapman and associates. Rich ore recently was found in an adit on the Ormous property, owned by J. F. Nenzel, at Limerick.

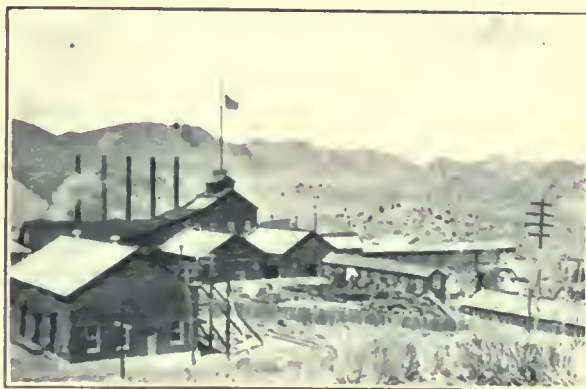

The annual report of the Seven Troughs Coalition M. Co. shows that during the year of 1911 a total of 4260 ft. of development work was done. The ore production

amounted to 3137 tons. The ore averaged \$125 for the year and \$203 in December. During the year a tailing dam, giving a storage capacity of 4500 tons, has been built, the cyanide plant constructed, and some new machinery placed in both mine and stamp-mill. The company has acquired 80% of the holdings of the Kindergarten Extension M. Co., adjoining its property, and the Fine Gold claim, on which the cyanide plant and tailing dam are situated.

STOREY COUNTY

The new 2460-ft. level pump station in the C. & C. shaft was completed last week. Measurements taken last Saturday show that the water has been held below the 2650-ft. level. The second drill-hole from the Ward raise in the Julia shaft cut into the old workings on the 2150-ft. level of the Bullion incline. When the ventilation equipment is completed, the pumping association will work south to a point where bulkhead No. 1 was constructed in 1882.

In the Union mine the north drift, 2500-ft. level, has reached quartz sampling about \$35 per ton. The Ophir company last week produced 329 tons of ore averaging \$42 per ton. The Ophir is the only company approaching

C. & C. SHAFT.

normal production, as the Mexican is waiting for the mill to start treating ore, repairs to the Union shaft have not been completed, and the Crown Point is delayed by changes and repairs to the Yellow Jacket hoist.

NEW MEXICO

OTERO COUNTY

The Eureka Mines Co., Con., has almost completed its annual work on its property. S. Howard Leech supervised the work. The Orogrande Smelting Co. also has about completed its work, but has a few men engaged at the By Chance property. C. K. Hartley has a small force working at the old Monte Carlo Con. Copper Co.'s property, which is now owned by another corporation. Messrs. Fink, Burnbeiser, and Baker, all of Oklahoma, are reported to have found gold ore on their recently purchased property, formerly known as the Knecker. George E. Moffett and associates, leasing the Monarch, near Lucky Flat, are mining good ore. George Creamer is doing annual work on his claim, near Cuprite, known as the Battle Axe.

SOCORRO COUNTY

(Special Correspondence.) The Socorro Mines mill handled between 5000 and 6000 tons of ore during December, yielding 33,000 oz. of gold and silver bullion and 10 tons of high-grade concentrate. The heavy snows have somewhat delayed the arrival of parts of the oil-engines for the new power equipment, which, however, will soon be in commission.

The Ernestine M. Co.'s clean-up for the last ten days of December resulted in 10,150 oz. of gold and silver bullion, with a concentrate product of 9000 lb. for the period. The past week's ore treatment was 525 tons. The crude-oil engines are being tested out prior to giving them the regular mill and mine load. Seventy tons of the Oaks Co.'s ore was treated the past two weeks in the Deadwood

mill, taken from development on the Pacific mine. At the Deep Down lessees are timbering the stopes preparatory to starting production.

Mogollon, January 12.

OREGON

JACKSON COUNTY

The Southern Oregon and Northern California Mining Congress will be held at Medford, February 2 and 3. An exhibit of ore and machinery will be one of the features of the meeting. Among other papers on the program will be one on 'The Public Land Question' by J. F. Callbreath, secretary of the American Mining Congress.

JOSEPHINE COUNTY

A shipment of gold recently was made from the Horsehead mine at Williams through J. H. Miller, a merchant of that place.

UTAH

BEAVER COUNTY

An assessment of $\frac{1}{2}$ c. per share has been levied on the stock of King David M. Co. to pay off the indebtedness of the company. The mine will not be opened before spring. Stock becomes delinquent February 13 and sales day will be March 6.

JUAB COUNTY

The Iron Blossom Con. M. Co. has declared a dividend of 7c. per share, payable January 25 to stockholders of record January 18. The dividend, which is the first to be declared by any Tintic property this year, will require the disbursement of \$70,000, a total to date of \$1,070,000.

Sinking the main shaft of the Eagle & Blue Bell mine was started under William Owens, superintendent of the property. Three shifts are working. Ore will be shipped as usual while the shaft is sunk.

SALT LAKE COUNTY

(Special Correspondence.)—Kirk & Leavell, of Salt Lake City, have taken a lease on that part of the Utah-Apex mine, Bingham district, above the 400-ft. level, which they will operate through the Phoenix and Andy adits. The lessees have a force of about 40 men employed. The ores carry lead, silver, gold, and copper, the first two and the last two named metals being in separate veins. Their low-grade ore is to be concentrated at the Winnemucca mill, operated by W. Ziegler. The Utah-Apex company is mining and milling ore from the levels below the 400-ft. level, taking the ore out through the Parvenu adit, which is on the level of the Phoenix mill. Kirk & Leavell are also working the Last Chance and Horace Greeley mines, situated farther up Carr fork in Bingham district. The Last Chance is noted as a producer of high-grade silver ore.

Salt Lake City, January 15.

The Utah Copper Co. is preparing to redeem \$2,778,050 of the bonds of the Bingham & Garfield railroad, converting them into Utah Copper stock at \$50 per share. This will increase the issued stock to 55,561 shares. The bonds are drawing 6%, and the Utah Copper Co. is paying 6% on its stock at \$50 per share.

The third section of the Ohio Copper Co.'s mill will be in operation by the end of the month. It is thought that the Wall crushers, 18 sets of which have been placed, will be sufficient to handle the ore for the third section, which will bring the capacity of the plant to about 3000 tons of ore per day.

The Utah-Apex M. Co., according to a recent report, is about to develop a much larger portion of its holdings in Bingham canyon through an extension of the Parvenu adit. The company is said to have been earning \$20,000 per month from its Bingham operations, and to have paid its floating indebtedness of about \$90,000. There is outstanding a bonded indebtedness of \$289,000, of which the convertible clause expired January 1. The 71,800 shares held for possible conversion, and \$70,000 more of authorized bonds never issued, are free for treasury use. It is said that the company is to increase its production by 50 per cent.

SUMMIT COUNTY

Press reports state that a new orebody has been found at the 1550-ft. level of the Silver King Consolidated mine at Park City. James Mara is superintendent of the property. During December 9118 tons of ore was shipped from Park City.

UINTA COUNTY

Samples from a deposit of phosphate discovered six months ago about 16 miles north of Vernal, have assayed about 80% phosphate, it is reported.

UTAH COUNTY

Operation has been resumed on the Santaquin King M. Co.'s property, in the Santaquin district, says a recent newspaper report.

CANADA

BRITISH COLUMBIA

The Nickel Plate mine in December established a new record for itself with a production for the month of 5514 tons of ore, against 5340 tons in November. The press report does not give figures regarding the recovery, but states that it was higher than ever before.

Officers of the British Columbia Platinum Co., Ltd., state that large deposits of platinum ore have been discovered on the company's property, Tulameen river, Similkameen district. Gilbert Blair, of Tulameen, is secretary-treasurer of the company.

George Clothier, general manager for the Indian Mines, Ltd., Portland Canal district, has denied rumors to the effect that the property had been sold.

ONTARIO

Returns from a car of ore from the 500-ft. level of the Temiskaming M. Co., Ltd., show 31 tons yielded 200,723 oz. silver, valued at \$110,000. This is one of the richest cars ever shipped from Cobalt and is regarded as significant, as it came from one of the lowest levels in the district.

During the year 1911, 24,831 tons of ore was shipped from the Cobalt district, according to newspaper reports. The amount is about 8000 tons less than for the preceding year. The decrease is accounted for by the fact that many mines have built concentrators for treating their own ores, assert the press despatches.

YUKON

(Special Correspondence.)—The recent discovery on Sixty-Mile river was made by a Swede named Matson, popularly known as the 'Lone Swede', at a point about 80 miles south of Dawson and 30 miles west of the Yukon river on an east-west line. He secured about \$40 from a hole which he drifted, cleaning up about 55 sq. ft. of bedrock. The whole district has been staked during the past two weeks. The valley is wide, and the ground is generally believed to be about 25 ft. deep. Matson drilled four holes, but found 'pay' in only one of them, and as he filled this hole, no one has been able to verify his find. It is certain at the present time that there is nothing to excite anyone.

Dawson, January 2.

Messrs. Butler, Nazarino, Vaglio, and Braga are reported to have found the second channel on the bench just off No. 20 on Barker creek. Equipment will be purchased to handle the deposit on a large scale.

MEXICO

CHIHUAHUA

The strike at the Santa Eulalia has been settled and the agitators, at the instance of the Government, have left the district. About 1500 miners returned to work after holding out for a 25% increase in pay, an eight-hour day, half-pay in case of injury and during incapacitation, and in case of death a sum to be fixed by law. The men returned at practically the same wages and with the same hours as before the strike. The managers have agreed among themselves to provide a suitable amount for the families of those who are incapacitated or killed while at work in the mines.

Petroleum Production in 1911

The production of the various oilfields in 1911 is estimated by the U. S. Geological Survey as below, the revised figures for 1910 being also given for comparison:

	1910.	1911.
	Barrels.	Barrels.
Appalaehian field	31,985,515	28,000,000
California	73,010,560	81,000,000
Kansas and Oklahoma.	53,157,386	56,000,000
Louisiana	6,841,395	10,000,000
Texas	8,899,266	9,000,000
Miscellaneous	35,661,926	33,000,000
Totals	209,556,048	217,000,000

The total production for the United States is between 215,000,000 and 220,000,000 bbl. The gain in a single State—California—is greater than the net gain shown for the country as a whole, the usual decline in the older districts offsetting the increase in the Middle West and South. The most striking feature of the year in the petroleum industry was the development of the Electra oilfield in northern Texas.

The petroleum trade as a whole has suffered of late from two antagonistic conditions. First, there has been over-supply due to the sudden development of great fields, first in one part of the country and then in another, until confidence became shaken as to the possibility of maintaining a satisfactory price. This condition has had an unfavorable effect on production in the older settled districts which have passed the gusher stage and yet are capable with fair prices of maintaining a reasonable output for many years. Second, the trade has been constantly handicapped by the fear lest the big producing districts should wane as rapidly as they have waxed, and leave a supply far below the capacity of the huge industrial plants designed to utilize such veritable floods of oil as have characterized late years.

For two years, however, discoveries of oilfields of great size have followed one another so closely that doubt has become conviction that the supply is abundant for years. It cannot be denied that the quality of geologic deduction has so changed for the better, thanks to more exact and intelligent field investigations, that the geologist's estimates of the oil resources are now more than generally accepted by the oil producers and users.

The tendency to substitute oil for coal in many industrial establishments is growing rapidly. It is further encouraged by the possibilities of still greater economies by burning oil in internal-combustion engines. Its advantages long known in the manufacture of fine glass are being heeded. It has been adopted by the Navy, and its use increases on the railroads. Oil is being taken seriously.

During the year stocks in general have declined except in California. In the Appalaehian field and in the Mid-Continent field they remained stationary. In Illinois there are about 21,000,000 bbl. in storage, compared with 27,000,000 in 1910. The stock on the Pacific Coast is estimated at 40,000,000 bbl., compared with only 33,000,000 at the close of 1910. In neither year is account taken of such producers' stored oil as has not been sold or even carefully measured, but is chiefly contained in open reservoirs.

According to the Bureau of Statistics of the Department of Commerce and Labor, the exports of crude oils increased from about 165,000,000 gal. for the first 11 months of 1910 to 183,000,000 gal. for the corresponding period of 1911; of naphthas, from about 92,000,000 to over 130,000,000 gal.; of illuminating oil, from 861,000,000 to 1,025,000,000 gal.; of lubricating oils, from 150,000,000 to 164,000,000 gal.; and of residuum, from 113,000,000 to 125,000,000 gal. In 1911 the Bureau of Statistics for the first time chronicled the importation of gasoline, 7,639,125 gal. being imported, principally from the Dutch East Indies. In 1911 the importation of other oils, chiefly crude oil from Mexico, amounted to 48,216,167 gal., worth \$1,640,514, in the first 11 months. In the corresponding period in 1910 such importations amounted to 23,924,571 gallons.

Among the Copper Mines

The Ray Con. Copper Co.'s production for 1911 is estimated at 15,500,000 lb. of copper. The April production was 704,000 lb., and from then the monthly production increased steadily to 2,660,000 lb. of copper for December. As the fifth unit of the mill recently was placed in commission, it is thought that the January production will show another increase.

Work at the Inspiration mine, Gila county, Arizona, is at present confined almost entirely to the operation of the experimental mill and the construction of a temporary warehouse at the mouth of the main adit. Work has been started on the water-supply dam across Pinal creek, and a boiler, engine, and head-frame have been rigged up on the Inspiration ranch, about five miles from the mine, preparatory to sinking a 2-compartment shaft for developing additional water-supply. Development of the Live Oak orebody is now confined entirely to underground work, all churn-drilling having been discontinued.

The copper production in February by the mines of the Butte district will show an increase. The Anaconda company's properties are making larger production, but it will be about the first week in the coming month before such mines as the East Butte and Tuolumne commence to show any increase. The Tuolumne has a very large body of ore blocked out, but owing to the lack of facilities, it was not in a position to do any better than 100 tons per day and carry on its other work. However, the new surface plant is about ready for operation, and by February 1 the production will be increased to 400 tons per day, which will be the largest amount of ore ever taken out of the mine daily.

The Butte-Alex Scott, which has been producing about 50 tons per day, has increased its output to 100 tons per day, and sufficient ore has been blocked out and is in sight to continue this increase for an indefinite time. It would not be surprising that if by the close of next month the production of all the mines of the district would be increased so that the total production would be in the vicinity of 27,000,000 or 28,000,000 lb. per month. This would mean that the Anaconda properties would be turning out about 25,000,000 lb. per month, and that among the Tuolumne, North Butte, East Butte, Butte-Alex Scott, and one or two other small mines, the remainder would be made up.

The East Butte company will also start on a scale of increased production about the first of the month.

The Guaranty Trust Co. of New York and Kidder, Peabody & Co. of Boston offer, until January 29, \$10 per share cash to stockholders of the Inspiration Copper Co., Gila county, Arizona, or an exchange of one share in the new Inspiration Con. Copper Co. for two shares of the older company. To the Live Oak Development Co. they offer \$10 cash per share, or two shares of new for every share of old stock. Six million dollars, 10-year, 6% bonds, convertible into stock of the new company at \$25 per share, will be offered to stockholders February 1. The bonds are payable, 25% March 1, and 25% each six months thereafter, until paid. The bonds will be issued at par. The company will erect a concentrator of 7500 tons nominal daily capacity, but with an actual capacity probably considerably higher. To provide for bond conversion, the erection of the concentrator, and to bring the mine to a state of production, not over 1,000,000 shares of the authorized capitalization of 1,500,000, par value \$20, will be issued. The annual production, according to recent estimates, will be 65,000,000 to 75,000,000 lb. of copper at a cost of about \$1 1/2c. per lb. The basis of consolidation was fixed by engineers, who estimated a total of 45,300,000 tons of ore averaging 2% copper.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

E. B. YERINGTON is here.
H. W. TURNER is in London.
JOSEPH ERRINGTON is at the Palace.
W. A. PRICHARD is in San Francisco.
W. H. STORMS has returned from Los Angeles.
WEBB SMITH was in San Francisco last Monday.
CHARLES R. GREGG, of Denver, is at the Fairmont.
A. M. CHAMBERLIN was in San Francisco this week.
E. R. SCHULEY, of Reno, Nevada, is in San Francisco.
CHARLES E. KENNEY is in San Francisco from Nevada.
E. V. BRAY has gone to Goldfield on professional business.
H. H. WILSON, of Tonopah, Nevada, is in San Francisco.
Z. KENDALL, of Manhattan, Nevada, is visiting San Francisco.

JAMES LAIDLAW, of Cranbrook, B. C., is at the Palace for the winter.

C. F. NOURSE has returned to San Francisco from Nacozari, Sonora, Mexico.

FREDERICK G. CLAPP is making a short visit to the oil and gas fields of Louisiana.

R. GORDON WALKER is in Mexico City for the Oliver Continuous Filter Company.

DUNCAN MACVICHIE has been appointed general manager for the Yerington Copper Co., at Yerington, Nevada.

RALPH ARNOLD, who recently returned from Trinidad, was in San Francisco this week and has gone to New York.

CLIFFORD G. DENNIS has returned to Berlin, Nevada, where he is installing a plant for the production of quicksilver.

E. P. RICE, of Wickenburg, Arizona, has removed to Miami, where he is connected with the Miami Copper Company.

PAUL W. PURTZMAN is visiting the California oilfields to complete the field work upon a bulletin of the State Mining Bureau.

A. A. PARE has gone to New Zealand and Australia to make an extensive study of mining and metallurgical methods.

The address is wanted of A. M. McDONALD and DAN McDONALD, twin brothers, who lived in Oakland about ten years ago.

R. B. BRINSMADE has opened an office as consulting mining engineer and metallurgist at 7 Meson del Angel at Pueblo, Mexico.

DANIEL GUGGENHEIM, MURRY GUGGENHEIM, and EDWARD BRUSH have retired from the board of directors of the National Lead Company.

R. B. MCGINNIS left San Francisco on January 15 for Yuma county, Arizona, to examine properties; he expects to return in two weeks.

HOWARD R. STEWART was married to Miss LENA BERYL BALL, in London, on January 2, and expects to visit California during February.

W. H. BRULE is consulting engineer and manager for the Summit Hill Mining Co., at Dobbins, California, with head offices in San Francisco.

J. N. HAUSER has accepted the position of superintendent of the properties at Carthage, Missouri, for the American Zinc, Lead & Smelting Company.

OSCAR WALLACE has resigned as manager of the Interstate mine, near Wallace, Idaho, and has taken charge of the Ruth property on Nine Mile creek, Idaho.

S. E. BRETHERTON will lecture on 'Modern Copper Smelting' before the Mining Association of the University of California, on January 24, at 8 p.m. in the Hearst Memorial building. Visitors are welcome.

STATISTICS regarding the iron trade in America are published fully by *The Iron Trade Review*. The iron industry has become so large and prompt knowledge so valuable that a daily edition is hereafter to be published.

CANADIAN and British mining engineers are to get together at Ottawa, March 6, 7, and 8, in a joint session of the Canadian Mining Institute and the Institution of Mining and Metallurgy. A number of Americans are planning to attend, professional knowledge, fortunately, being one of the things regarding which Canadians and Americans agree there shall be full reciprocity.

IT IS announced that Mr. William C. Hook, now circuit judge of the Eighth Judicial Circuit, will be appointed to the existing vacancy upon the bench of the Supreme Court of the United States. This puts an end to the widely expressed hope that a jurist especially versed in mining law might succeed to the vacancy. The Mining and Metallurgical Society of America has recently been in process of making a recommendation to that effect, but meanwhile the vacancy was filled.

STEADINESS and responsibility among employees is universally appreciated, and large companies are quick to utilize any factor that may tend to increase these desirable characteristics. The Anaconda Copper Mining Company has announced that henceforth it will employ only citizens of Butte, so long as a sufficient supply of laborers shall be locally available. This is a wise policy, for miners are too often Ishmaelitic in their characteristics, and anything which puts a premium upon steadiness, thrift, and sobriety will work to the advantage of the employer as well as of the community.

NEW producers of copper in the Southwest are making excellent progress. At the Chino two sections of the mill are in steady operation, and a third is expected to start early in February. At the Ray, which began production in April last, over 15,000,000 pounds of copper was produced during the nine months, the December output being 2,660,000 pounds. At the Miami the sixth unit of the mill is expected to start by February 1. The December output of this company was 3400 tons of concentrate, or approximately 2,500,000 pounds of copper, and about 2500 tons of 2.6 per cent copper is now being handled daily.

SUBSCRIPTIONS for the Emmons memorial fellowship in economic geology at Columbia University are being received from individuals in many lands. This is as it should be, since, aside from the fact that S. F. Emmons benefited men in many districts, the memorial is intended to be a tribute of mining men to the work of economic geologists. The men who brought science down into the mine and made it useful deserve well of their professional associates, and in honoring Emmons the whole rank of mining geologists is honored. If you have not already sent in your subscription, please do so. The treasurer is Mr. B. B. Lawrence, 60 Wall street, New York City.

FOREST fires are being better controlled, as is shown by the report of the district forester stationed at San Francisco, covering the year 1911. Although there were 797 fires, as against 553 the year before, the acreage burned was decreased 75 per cent. This is accounted for by the fact that 40 per cent of the fires were sighted, reported, reached, and controlled promptly, in place of 23 per cent the year before. More trails, telephones, and a better patrol service are accomplishing this result, and in this as in other matters prevention is proving better than the most vigorous attempts to cure.

AN unusual case was recently adjudicated by the Commonwealth High Court at Sydney, Australia. Thomas Johnson sued the English & Australian Copper Company, for which he had been manager, for wrongful dismissal. At the trial it appeared that the defendant company had bought a lot of copper ore, which was assayed as usual by both seller and buyer. The buyer's analysis, which was finished first, showed 36.24 per cent copper, the seller's analysis, when received, indicated 35.75 per cent. The manager thereupon instructed the buyer's assayer to make a new certificate for 35.85 per cent copper, which was then sent to the seller. When this was discovered by his company he was dismissed, and the suit followed. On the first trial damages of £1225 were awarded, but this was reversed on appeal. Corporations are commonly believed to have no souls; apparently the consciences of some companies are more tender than those of their officers.

THERE is a saying to the effect that anything that is worth doing is worth doing well, which may be adequately answered by asking, 'How well?' Accuracy is always desirable and frequently necessary; the same may be said of expedition. Often one can only be gained at the expense of the other, the securing of an adequate measure of both offers scope for the judgment and skill of the engineer. Elsewhere in this issue Mr. A. J. Sale discusses rapid methods for the determination of copper, in which accuracy is consonant with speed. Where the material to be thus assayed varies but little in character and copper content, it is often convenient to prepare a large sample of ore, approximating the average, which, after careful analysis by electrolysis, can be employed as a standard ore in place of copper foil, which is less convenient to weigh, and lacks the impurities present in the ore. Many such details of practice are everywhere being worked out as incidents of the day's work in the mining world, and the engineer who is quick to learn is also generous to share his knowledge with others and thus aid in keeping the wheel of progress steadily advancing.

Why Not Mine?

A visitor from abroad, when examining the mining districts of the United States, is likely to be impressed by the considerable areas on which but little exploratory work has been done, and may inquire if the small amount of work apparently performed has been sufficient to demonstrate the non-productive character of the ground. His mystification would be increased rather than lessened upon being informed that the ground in question had been located as mining claims, and in many cases patented, but no further development work had been performed. "But I understood that the purpose of your American mining law was to allow the individual citizen to freely develop mineral deposits upon the public domain; that any citizen might locate claims, if he proved their value as mineral-bearing land he might purchase them for a small sum, and if he was unable to prove their value they reverted to the

public domain; how then can large areas exist which are not open to location, and have neither been proved valuable nor valueless as mineral land?" Most probably the person interrogated would at this point give up in despair of ever clearly explaining how the American mining law, intended to permit exploitation of the national resources upon the simplest terms, has succeeded in producing confusion of rights beyond the wildest ideas of its framers, merely through having been made too simple through a faulty conception of the nature of ore deposits. It is a curious fact that the attempt to apply a simple system to a complex matter always results in the compounding of complexities. Thus the American mining law, conceived with the idea of making the development of mineral deposits as easy as possible, has really acted as a powerful retarder in their exploitation.

To attempt a general criticism of our Federal mining law is much like shooting at a flock of ducks, and is likely to be similarly ineffective. Let us therefore single out a bird, and direct our aim at it. Perhaps the most obvious is the curious outcome of the attempt in the law to secure free scope for initiative and stable rights to the prospector and miner. This was to have been obtained by providing that all the mineral land of the public domain should be freely open to prospectors; that when a prospector found indisputable evidence of the occurrence of a deposit he might secure a temporary title to a sufficient area to protect him while he explored it sufficiently to demonstrate its probable valuable or valueless character; and that, finally, he might for a small sum secure an absolute title to the property when he should have convinced himself that its probable value would justify the expense. Apparently this is ideally simple, yet in practice it has proved woefully ineffective, not primarily from defects in the law, but from defective machinery provided for its execution.

One of the important factors in the devising of an experimental system of government for the Republic was a horror of conferring power on officials. Men familiar with the medieval abuse of power in Europe by nobility and officials who were responsible only to a king whom they often did not obey and a God whom they did not fear, not unnaturally hesitated to confer upon officials any powers which might be retained by the community, and thereby escaped known evils by falling into unknown ones. The New England town meeting represents the eighteenth century idea of satisfactory government in the United States, and it is perhaps only because no ordinary imagination could conceive the growth of the United States during the next century and a half, that we find a system that was excellent for a New England town so unsatisfactory when applied to a nation imperial in its extent and resources. In short, from a twentieth century viewpoint the system of government of the United States is unbusinesslike. If in the conduct of an ordinary business every question that arose in the course of daily operations had to be submitted to a committee of shareholders for prolonged investigation and decision, it is obvious that the number of decisions coming before the shareholders would be more than they could adequately attend to, thus creating great delay. Department heads, rather than be kept waiting for months and years to find whether apparently necessary courses of action would be sanctioned or not, would either devise irregular methods of conduct of affairs which would obviate the constant necessity of submitting oftentimes trivial matters for investigation and decision, or would restrict their activities as much as possible. Progress and initiative would be deadened, the business would tend toward a dull round of 'red tape' and would unquestionably fall into confusion. No business man would countenance this in the conduct of a private business, yet we all countenance it in our public system of

government. In the specific case which we are discussing, if a question arises as to the validity of a claim it must go before a court for decision, with the right of appeal almost indefinitely prolonged. The result of this is that when anyone has located a claim it is not really worth any other person's while to attempt to question that right unless the claim gives evidence of much value, when the slightest pretext will suffice for a prolonged controversy that too frequently leaves both sides in a position where nothing effective can be done for the development of the deposit. Disputes as to mineral rights on unpatented claims should be subject to the review and decision of a single official, who would immediately award the claim to one or the other of the disputants, thus releasing the energies of both from a fruitless controversy to engage in useful development. The rights involved are not ordinarily great enough to justify buttressing them with elaborate machinery. Even if now and then, through too hasty decision, a prospector lost a claim to which he was justly entitled, the pecuniary loss would commonly be less than a miner often incurs in an evening about the faro or poker table. On the other hand, he would be freed from a hampering quarrel and could put his best efforts into making fresh discoveries. The suggestion that 'graft' would be the result of putting such power into the hands of a single man is patently absurd. 'Graft' results when a little man is in a position to do a big favor to a corporation or an individual; there is clearly no chance, for it where but little money is involved. If the general system remain as it is now what the prospector needs is more freedom and less protection in his right, then large areas of mineral land can not be held under questionable titles by those who are not developing them and who are unwilling to let them go. Let us be done with law-suits—why not mine?

Leasing Agricultural and Mineral Lands

Opponents of a leasing system as applied to the public mineral lands are accustomed to ask why the system, if it is to be applied to mines, should not also be extended to cover farms—why mineral lands only, and not all public lands, should be leased. The question is raised not in order to promote leasing of the agricultural lands, but to prove, or attempt to prove, that no leasing system is desirable in America. We have already expressed our favorable opinion of leasing when applied to coal, phosphate, and oil lands. We are by no means sure we would not favor a similar system for all mineral lands if a specific proposal that seemed sound should be urged. As to that, for the present, we reserve opinion. We do not, however, accept the dictum that advocacy of leasing as applied to certain lands necessarily commits us to advocacy of a similar system for all. Specifically, we do not favor the leasing of agricultural lands, and to our way of thinking there is a vast difference between the two proposals.

A farm is essentially a homestead; a mine is essentially a hole in the ground. The one is a place of habitation for all time to come; the other is a place temporarily occupied for a specific purpose. Farms, it is true, may, by reason of wrong methods of cultivation, 'run out' and be abandoned; but, even so, they may under changed conditions be brought again under cultivation, and there is no inherent reason why any farm should permanently cease to be of value. The farmer lives on the interest of his investment, and, if he be a wise farmer, his capital account, represented by the value of his land, increases as the years pass. The miner, on the other hand, acquires a piece of ground for the specific purpose of taking out and selling something which cannot be replaced. No matter how wisely he may plan, nor how carefully he may work, he draws on capital account from the day he first strikes a pick

into the ground to that when he regretfully hoists out the last man and shuts off the steam. Many mines are temporarily closed, and all mines must ultimately be expected to be permanently closed. In the one case the worker builds a continuing business, in the other he tears down and takes away—and in most instances the more efficiently he does his work the quicker he mines out the ore and moves on. Granting freely that the best social system is that which most firmly attaches men to the soil, granting further and gladly that a system of permanent tenantry is unthinkable in America, it does not seem illogical to argue for different systems of control in the two cases depicted. Clearly, a man may buy things out of income that are unwarrantably expensive when purchased out of capital. Giving men homes is one thing, and a thing that cannot be too greatly encouraged, but allowing them to lock up and keep from others capital which should be brought out and put into circulation is certainly different.

The wisdom or folly of introducing a leasing system for any lands will depend upon the particular plan adopted and the way in which it is administered. It is easy to imagine a system of leasing or a character of administration that would be fatal to all immediate development; but it is also possible to think out a system that would relieve many present difficulties, safeguard the future, and promote development. Whatever may be done should only be with full knowledge of conditions in the West, the territory to be mainly affected, and any changes made should not be radical. It is entirely possible to introduce a leasing system which will retain to the Government the right to alter conditions at some specified date in the future, and yet not unreasonably change the actual operating conditions now. If the results are satisfactory, further changes can be made as occasion arises. This is not possible under the present system of land tenure. A claim once patented belongs to the owner to do with as he likes; he may work it or not work it, he may make it useful or useless to the community. He may make it a centre of industry or he may hold it and block the way of others who would do so. The only remedy is taxation and possibly condemnation and repurchase by the public. Opponents of change too often blink present evils, which are in fact real and widespread. Their nature and effect has perhaps been sufficiently indicated. Some remedy must be found, and it will not do to dismiss without consideration one that is proposed, because of a fancied resemblance to the feudal system of farm tenure.

When Mr. Roosevelt began making land withdrawals, and when Congress took up the matter of validation of the withdrawals, a mighty storm of protest went up from the California oilfields. The net result, however, was undoubtedly good. No candid observer can doubt that the condition of the oil men there would today be the worse if public land was still open to unlimited staking. Furthermore, all legitimate explorers have, under the withdrawal act, protection they never had before, so long as their operations are conducted in good faith. Evidently the terms of the law are more important than its title. Recently a letter was sent to more than fifty representative mining men throughout the United States requesting an expression of opinion regarding the advisability of applying a leasing system to the public mineral lands. Four-fifths of the men replied, and all shades of opinion were expressed. It is interesting to note that nearly two-thirds favored some form of leasing. He is but a poor judge of public opinion who does not see that sentiment in favor of such a change is rapidly rising. It should be the part of mining men to inform themselves, to take a part, and to direct the framing of the new law when it is passed. Not leasing, but the particular form of leasing is important.

Copper Mining in the Caucasus

By FREDERIC W. CAULDWELL

*American capital is largely interested in the Caucasus Copper Co., Ltd., which was formed in London in 1900 for the purpose of taking over and developing copper mines in Murgne Gorge district of Artoin, near Dzansul and about 50 miles from Batum, which had been worked in the time of the Genoese, several centuries ago.

Up to the present time the company has expended large sums on the property, but only recently has it been brought to a stage where the plant will pay operating expenses and yield a margin of profit. The development of the mining property has been slow because the ore is most difficult to treat, the copper being so finely disseminated through the rock that fine crushing is required. A magnetic plant was first erected, but was found unsatisfactory, partly because of the difficulty of cooling large quantities of hot ore to the temperature required by the magnetic machines, and partly because of the difficulty in separating the ore from the silica. Enough of the latter mineral remained attached to render the concentrate produced too silicious for economical smelting. Water concentration is now being used successfully. It yields a concentrate that can be smelted with less than 15% of oil and gives a recovery comparable to similar plants in Utah and Nevada.

At the present time an extensive campaign of development is about to start at the mine, and one plant extension is already under way. It is proposed to increase the crushing, concentrating, roasting, and smelting equipment to a capacity of treating 1500 and probably 2000 tons of ore per day. The plant now treats 500 tons of ore per day. In view of these intended extensions, a description of the equipment and operation of the present plant is given. The mines contain, so far as is known from development work already done, 5,000,000 tons of 3¼% copper ore. It is known that there are extensions to this body far beyond that tonnage which have never been developed, as the ore now known is sufficient for present needs.

The ore occurs on a steep mountain-side in a flat body varying in thickness from 80 to 120 ft. The overburden to be removed amounts to one-third of a ton for each ton of ore developed. The whole of the tonnage of ore thus far developed can be mined in open cuts. It is planned to remove the overburden, 80% of which is soft earth, by means of hydraulic giants, which will be cheaper than steam-shovel work. These conditions, in connection with the cheap labor, will permit of an exceptionally low cost for mining, which, with a tonnage of 1500 tons per day, would probably equal the lowest cost obtained at the large porphyry mines in Utah, Nevada, or Arizona. With the mines opened and the overburden removed, it is estimated 2000 or 3000 tons of ore can be supplied daily to a concentrator.

The ore is carried from the mine in 4-ton double-hopper cars by a short track to a crushing mill having a capacity of 1200 tons per day. This mill contains four 18 by 24-in. Blake crushers and eight sets of 15 by 36-in. rigid rolls. Automatic feeders supply the first pair of crushers, which crush to 2½-in. maximum size. The ore is then carried on a Robins belt-conveyor to a 500-ton bin, above the second pair of crushers, which crush to 1½ in. Automatic feeders are also employed here. From the Blake crushers the ore is carried on a belt-conveyor to a bucket elevator, at the top of which it is discharged to the two units comprising the eight sets of rolls. Each set of rolls is equipped with its own elevator and trommel, so that the material already fine enough to pass through the trommel is not sent through the corresponding set of rolls, thus decreasing the formation of slime. The first set of rolls has a ¾-in. trommel, the medium roll a ¾-in. trommel, and the two pairs of fine rolls each a 5-mm. (millimetre = .039 in.) trommel.

The ore, crushed to a 5-mm. size, is delivered to an

aerial ropeway of the Pohlrig system, similar to the Bleichert system in use in the United States, and carried to the concentrators at a level 2400 ft. lower. There it is divided between two concentrators, each having a capacity of 250 tons every 24 hours, and is fed from stock bins by automatic feeders to the boot of a vertical elevator, at the top of which a stream of water carries the ore to six jigs. In these all sizes of ore below 5 mm. are jigged. The tailing from the six jigs goes to revolving screens with 1½-mm. holes, from which the oversize goes to an Evans-Waddell Chilean mill, equipped with 1½-mm. screens. The product of this Chilean mill joins the undersize from the revolving screens and is elevated by a bucket elevator to a 3-compartment hydraulic classifier. The coarsest spigot from this classifier is sent to four jigs, and the tailing from these jigs goes to a second Chilean mill equipped with ¾-mm. screens.

The ore from the other compartments of the classifier is sent to a row of ten 6-ft. Frue vanners. The pulp is divided over the vanners in the proportion required by the tonnage produced in each of the sizes of the hydraulic classifiers. Each of these 10 vanners thus treats between 20 and 25 tons of ore per day. The tailing from each group of these first-treatment vanners goes to a bucket elevator attached to each group. After being elevated, the tailing is again classified and treated a second time, a group of 20 vanners re-treating the tailing from the first 10. A fourth row of 10 vanners is used to give a double treatment to the slime obtained from the overflow of the classifier. The slime is collected in eight wooden tanks, 10 ft. in diameter and 18 ft. high. The concentrate produced averages approximately 8½% copper, 37% silica, and 28% sulphur. It is sent to concentrate-storage bins and from there delivered to McDougall roasters, 18 ft. in diameter, and of the usual type used in the large copper mills of the United States. The red-hot calcine, mixed with limestone, is delivered to three reverberatory smelting furnaces, two of which are 35 ft. in length and one 50 ft. All are fired with oil.

The property is equipped with an excellent machine-shop and a foundry of a size usually found only in plants of several times the capacity of this. These large shops are found necessary, owing to the distance and time required to obtain spare parts. The mines and smelter use oil for fuel exclusively. The oil is brought 50 miles from Batum by the company's own pipe-line through 4-in. Mannesmann high-pressure pipes. The oil used is that produced in the Caspian oilfields and is brought from Baku to Batum in tank cars. The concentrators include the most up-to-date American machinery. In the smelter and the crushing mill the machinery is partly of English and partly of American manufacture of the most improved types. In extending the plant, the company will install equipment on the same general lines as that now in use.

At the present time over 1100 men are employed in the mines and the smelting work and in construction. The labor is cheap and fairly efficient. A great variety of nationalities is found at work in the different departments. The miners are chiefly Greeks and Turks, with Persians working in the crushing mill. At the concentrators the laborers are Russians, Turks, and Georgians. In the machine-shop and foundry Russians and Georgians are to be found almost exclusively, while at the smelter the labor is exclusively Persian.

The property is about 50 miles from the seaport of Batum. The Government macadamized military road covers 35 miles of this distance and the remaining 14 miles the company was obliged to construct at great expense. This road had to be built along the face of mountains through rock and sliding soil. During the 10 years of its existence the company has conveyed in wagons 100,000 tons of supplies, machinery, and product over this 50 miles of road. All the copper produced by the company is sold in Russia and commands a good price, as the duty on foreign copper imported into Russia is 5 rubles (\$2.575) per pood (36.1 lb.). The property, in point of ore tonnage developed, is today one of the large mines of the world.

*Abstract from *Daily Consular and Trade Reports*.

The Spring Valley Oilfield in Southwestern Wyoming

By F. J. H. MERRILL

This field is in southern Uinta county, Wyoming, near the line of the Union Pacific railway. Its geologic structure was worked out with much care by A. C. Veatch and assistants in 1905 and 1906, and the results were published in Bulletin 285 and Professional Paper No. 56 of the U. S. Geological Survey. To these publications, especially the latter, the reader is referred for minute details. The general facts of importance to the present discussion are as follows.

In the vicinity of Spring Valley the members of the Cretaceous series, which carry coal at several levels, are

been eroded away, leaving exposed the underlying red beds of the Jurassic, and to the eastward, upon the axial exposure of Jurassic and the edges of the Cretaceous strata, has been laid down a great thickness of Eocene Tertiary beds included in the Wasatch group and known individually as the Almy, Fowkes, and Knight formations, having an aggregate thickness of 5000 to 6000 ft. These Eocene beds dip eastward about 20°, extending for miles in the same direction, in unbroken benches and plateaus.

No Cretaceous strata are exposed east of the anticlinal axis, and no information is available as to the level of

VIEW ACROSS SPRING VALLEY ANTICLINE, NORTH OF LEROY STATION.

folded in an anticline with northeasterly axial trend. This is succeeded on the west by a synclinal fold, the west limb of which is overturned to the east and adjoins on the west an extensive fault also trending northeasterly.

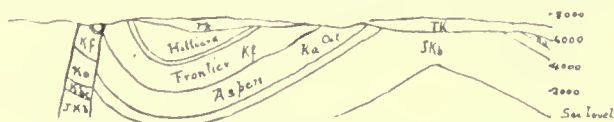

Near the base of the Cretaceous is a formation called the Aspen shale, 1800 to 2200 ft. thick, having intercalated beds of sandstone varying in thickness up to 60 ft. which, on the west dip of the anticline, carry nearly all the petroleum found in this region. At one point oil has been found in the underlying Bear River sandstones, which are about 2400 ft. thick and form the base of the Cretaceous, resting directly on the Jurassic red sandstones.

The productive oilfields lie on the west limb of the anticline between the outcrop of the Aspen shale and the axis of the syncline. But while a synclinal axis theoretically offers opportunity for the accumulation of oil, it happens that along the axis of this particular syncline, in the vicinity of Spring Valley, the top of the Aspen shale lies at depths of 2000 to 4000 ft. below the surface. As this formation is about 2000 ft. thick and the exact level of the oil-sand is not known, it will be seen that along this axis wells 3500 to 5500 ft. deep will be required to reach oil. Further, it is possible that the pressure of this great thickness of strata may have compacted the sandstones along the axis and reduced their porosity. If this be true, better opportunities may be found on the west dip of the anticline.

Along the axis of the anticline the Cretaceous beds have

the buried surface of the Cretaceous or the thickness of the Tertiary beds which overlie it. The accompanying section shows this structure in diagrammatic form.

East of the anticlinal axis the eroded surface of the Cretaceous is covered unconformably and deeply by the

SECTION ACROSS SPRING VALLEY ANTICLINE.
(After A. C. Veatch.)

Eocene Tertiary beds, and the existence of oil in the Aspen shales has not been proved.

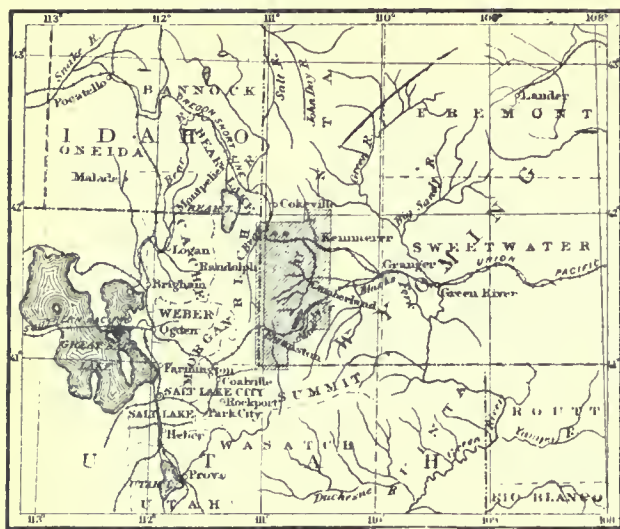

No wells have yet been sunk through these Tertiary beds to determine the line of outcrop of the Aspen formation on the old surface of the Cretaceous. Further, while the presence of oil in the Aspen formation on the east limb of the anticline is in every way probable, it cannot be regarded as certain, since there are geologic possibilities that might interfere with it. Therefore, concerning this territory east of the axis, information is lacking on the most important points. These are: (a) the thickness of the Tertiary deposits overlying the upturned edges of the Cretaceous beds; (b) the distance east of the anticlinal axis at which the Aspen shale outcropped on the old sur-

face, now buried—it is obvious that the deeper the erosion of the Cretaceous the greater would be the thickness of the overlying Tertiary below the present surface and the greater the distance of the buried Aspen outcrop to the east of the antilinal axis; (c) the presence of oil east of the anticline in the Aspen shale or in any other formation.

On the last point, about all that can be said is, that oil will probably be found in this formation, but the number of wells that must be drilled on any particular section line across the strike, in order to find oil, or the depth at which it may be found, is wholly conjectural.

The region east of the antilene, therefore, offers possibilities as an oilfield, but will require extensive exploration.

There are but two seepages in the Spring Valley region. One, called the Brigham Young oil spring, was known to the Mormons in 1847, and is situated near Hilliard, on the N.E. $\frac{1}{4}$ of the N.W. $\frac{1}{4}$ of Section 4, T. 13 N., R. 119 W. The other, known as the White oil spring, is on the S.E. $\frac{1}{4}$ of the N.W. $\frac{1}{4}$ of Section 33, T. 14 N., R. 119 W. This was discovered in 1867. The Carter oil spring, on the S.W. $\frac{1}{4}$ of the N.E. $\frac{1}{4}$ of Section 31, T. 14 N., R. 119 W., was started in 1868 by opening a

SOUTHERN WYOMING OIL TERRITORY.
(Spring Valley field in black near railway.)

small adit for coal. This oil had a gravity of 21°B. In 1900 a well was sunk by the Union Pacific Railway Co. about one-half mile southwest of Spring Valley station, and yielded oil at three levels, 491 to 493 ft., 573 to 581 ft., and 1148 to 1170 ft. With the exception of the wells drilled through the Aspen shale into the Bear River formation, all the wells of the productive field take their oil from sandstone layers in the Aspen shales. These sands vary in thickness and in number, as shown by the table of well records. It is said that the wells at the north end of the developed field have thicker beds of oil-sand than those at the south end, and this seems to be the case.

An extensive and detailed set of well records from this field has been published in Professional Paper No. 56, pp. 139 to 159. Since the paper was issued, but few wells have been drilled, the most important being those of the Texas King Oil Co. and that of the Roberts Oil Co. In Texas King well No. 1, the top of the oil sand was reached at 758 ft. The bottom of the well is 20 ft. below. The Roberts well No. 1 met oil at 840 ft., with 20 ft. of oil-sand.

The oil of this field as it flows from the pumps, is free from sand. The oil-sands are evidently, therefore, more coherent than those in California and Texas, where the oil carries a considerable percentage of its bulk in fine sand. The earlier wells drilled in this field were cased to the bottom of the sand, and the casings, according to California practice, were perforated at the points where oil-sand was detected.

In all cases, while the wells when first brought in have yielded from 60 to 130 bbl., within a few months they have fallen off to a production of from 5 to 15 bbl. per day. The drillers explain the falling off of the flow by the suggestion that paraffine is deposited in the perforations through evaporation of the volatile constituents when the wells are pumped dry. This paraffine can be melted out by the use of steam or hot water. During the past year three wells were drilled, in which the casing stopped at the top of the oil-sand. In these also, the flow, while copious at the beginning, shrank very greatly; in one case from 124 bbl. per day at the outset to 16 bbl. Evidently, therefore, if deposition of paraffine is the cause of the decrease in flow, it must occur in the pores of the oil-sand. The suggestion is now made that the flow can be restored by shooting with nitroglycerine. This, however, has been tried, in one case, without permanent results. Until, therefore, some one succeeds in maintaining the flow of a well, it is not certain that this can be done, and the field may, at present, be regarded as one of uniformly small production. The Pittsburg-Salt Lake Oil Co. has five wells which were drilled some years ago, and the average production of these wells is about 4 bbl. each per day. The present output of the whole Spring Valley field is only 100 bbl. daily from a total of 16 producing wells, or an average of 6.6 bbl. per well per day. At a market price of \$1.60 per bbl., this corresponds in income to a production of 35.2 bbl. per well per day of California fuel oil at 30c. Oil of high gravity and value, theoretically costs less to market, because the transportation charges are proportionally lower.

The oil of the Spring Valley field varies in gravity from 41 to 49°B. It is not always carefully handled and, when pumped into uncovered wooden tanks, loses 3 to 4°B. by evaporation. When it reaches the refinery its gravity is said to be from 41 to 45°B. As stated by the Utah Refining Co., the oil contains on an average: gasoline, 15%; kerosene, 45%; lubricating oil, 40 per cent.

An analysis made of one of these oils by a Boston chemist gave the following results:

	Per cent.
Light naphtha	10.67
Illuminating oils	34.67
Lubricating oils	41.16
Residue, largely paraffine	13.50

As all the Spring Valley oil is adapted to refining, its natural market is a refinery. At present all oil brought to the railroad at Spring Valley and Leroy goes to the refinery of the Utah Refining Co. at Salt Lake City. The same company controls a small refinery near Spring Valley station which is not now in operation. A refining plant brought to Leroy from a locality near San Francisco, California, is being erected, but has not yet begun systematic operations.

The Pittsburg-Salt Lake Oil Co. has pipe-lines from Spring Valley to all the producing properties except that of the Standard Reserve Oil Co. A gravity pipe-line has been laid from the wells of the latter company to Leroy, where at present this oil is loaded into tank-cars and shipped to Salt Lake City.

The Utah Refining Co., through its purchasing company, the Pittsburg-Salt Lake Oil Co., pays at the well \$1.60 per bbl. for oil of 41°B. gravity or higher. For oil below 41°B., 5c. per degree is deducted from this price. The two refineries of the Utah Refining Co. are said to have a total capacity of 1000 bbl. daily, but the total supply is only 100 bbl. daily, which is all treated at the Salt Lake City refinery. The refinery at Leroy proposes to pay \$1.75 per bbl. for 43°B. oil; adding or deducting 5c. per degree above or below. It has been suggested that the product of this field might be profitably shipped to the Standard Oil Co.'s refinery at Florence, Colorado, or to that at Boulder, but I have not had opportunity to verify the possibility of this.

The costs of operation in this region are difficult to ascertain, because there has been no systematic study of this detail by the operating corporations. Apparently con-

ditions are similar to those in California. Many of the wells furnish enough gas for making steam, and when this is lacking, good steam coal can be had in the vicinity for \$1.75 per ton.

For drilling, as in California, the standard rig is found most substantial. To drill a first well 1000 ft. deep will cost about \$10,000. If other similar wells are to be drilled nearby, they can be put down for about \$6000 each.

The companies now operating are: Pittsburg-Salt Lake Oil Co., Salt Lake City, 5 wells, 1200 to 1500 ft. deep; Texas King Oil Co., Evanston, Wyoming, 2 wells, 800 ft. deep (No. 1 well oil-sand 758 to 788 ft.); Roberts Oil Co., Evanston, Wyoming, 1 well, oil-sand 840 to 860 ft., two 5-ft. sands below; International Consolidated Oil Co., Boston, Massachusetts, 5 wells; Standard Reserve Oil Co., Chicago, Illinois, 4 wells. Those not producing are: Duchess Oil Co., Spring Valley, Wyoming; Manhattan Oil Co., Evanston, Wyoming; Alleghany Oil Co., Evanston, Wyoming; International Petroleum & Oil Development Company.

Accurate 'Slop-Coppers'

By A. J. SALE

The volume of work around large copper mines and mills, necessitating the employment of a system of assaying for mine or drill samples which is more rapid than the iodide or electrolytic methods, naturally forces the assayer to fall back on the so-called 'slop-coppers.' But the average chemist is apt to conceive the idea that slop-coppers means sloppy coppers, and works in accordance. The 'slop' method, if proper precautions are observed, will give accurate results even on low-grade refractory ores.

The first consideration for accurate work is that, with ore assaying from 1 to 3%, the amount of copper contained in the ore is relatively so small that from a 1 gm. assay the solution will be so dilute at the time of titration that it will be difficult to obtain an accurate end-point. By starting with 2 gm. I consider that the large bulk of material handled in the assay is more than compensated for by the advantages obtained. The next important consideration is that some portion of the copper is usually closely associated with the iron pyrite, which is far more soluble in aqua regia than in nitric acid. The course of operations that I have found to give best results is to put 2 gm. of pulp (through a 100-mesh screen) into a casserole and boil nearly to dryness with 15 c.c. of aqua regia. Then add 10 c.c. of nitric acid and boil until it becomes fairly syrupy. Then add about $\frac{1}{2}$ gm. of chlorate of potash and boil for five or six minutes. This will sometimes throw down a dark brown precipitate which is probably mostly manganese dioxide. I have found from a large number of results that the proper manipulation of chlorate will always prevent the yellow precipitate which sometimes forms when titrating, and causes difficulty in reading the end-point.

The assay is washed from the casserole into a small beaker with boiling water and allowed to cool until it will not 'spit' too violently when ammonia is added. The ammonia is put in, a little at a time with constant stirring, until the iron is completely precipitated. It is very poor practice to add ammonia directly in the casserole, as it is then difficult to see the precipitate, also to wash it out.

The assay is now filtered into a titrating flask and the precipitated iron washed with boiling water. This iron always contains some of the copper present and should be washed into a beaker and nitric acid added drop by drop until the precipitate is almost dissolved. It is usually better not to completely dissolve it, as this may again put the manganese into solution. Ammonia is now added until all of the iron is re-precipitated, and then the material is filtered through the same paper into the titration flask. The precipitate is washed with boiling water, and if the filter paper shows any signs of blue color the re-solution and re-precipitation is again repeated.

For standardizing, the best results are obtained when the amount of copper in the standard is approximately the same

as in the assay; for instance, if the ore runs 3% the assay from 2 gm. will contain 60 mg. of copper, which should be approximated when weighing the standard. Also it is more accurate to add approximately the same amount of foreign elements to the standard as will occur in the ore and carry it through the same as if it were an assay. It is more rapid to find the exact weight of a piece of copper than to try to cut it to some exact weight, such as 40 or 50 mg., only, as before stated, it should be approximately of the same weight as the copper in the assay. If we start with 2 gm. of pulp, then each 20 mg. of copper is equivalent to 1%. It is much less confusing to divide the weight of the standard by 20 and record as an equivalent percentage than to keep its exact weight. For instance, if the weight is 44.6 mg., record as 2.23%. Two standards should be weighed and one titrated at the beginning of a set of assays and the other at the finish. In titrating, the solution should be at the temperature of the room and the same amount of time and agitation given to each. It is also better to stop at a light pink end-point than to take out all the color; the important thing is to have the same end-point for all assays and standards. To avoid errors in calculation, the results should be recorded in the form shown below:

	No.	Burette reading.	Net reading.	Percentage copper.
2.76%	standard.....	10.15	10.15	0.272 per c.c.
	1	21.0	10.85	2.96
	2	30.6	9.6	2.62
	3	41.35	10.75	2.94
	4	50.7	9.35	2.55
2.15%	standard.....	58.55	7.85	0.274 per c.c.

The mean strength will be 0.273% copper per c.c. In rapid work there is possibility of an error of subtraction or multiplication; a quick check on the arithmetic is obtained by adding the final assays. The sum of these should equal their total net burette reading, times the mean strength of solution. In the above table the sum of the assays from No. 1 to No. 4 is 11.07%, and the total net burette reading is $50.7 - 10.15 = 40.55$ c.c. Now, $40.55 \times 0.273 = 11.07$, which checks the calculations.

The water used in the analysis is an item of considerable importance. Most of the so-called 'distilled' water around a mine or mill is condensed steam, and frequently contains oil or boiler compounds which may seriously affect the results. The most satisfactory water that I have found, where pure distilled water is not obtainable, is secured by adding a little ammonia to ordinary spring or hydrant water and boiling until all of the excess of ammonia is gone. This, when decanted from the precipitated lime and other salts, will nearly always give a good end-point. The final precaution for good results is the use of pure potassium cyanide. I have found from a number of experiments with partly decomposed cyanide that its strength is liable to vary with the part of the burette from which it is drawn, being stronger at the bottom of the burette than at the top, or the reverse. These precautions may seem to be trivial, but on refractory low-grade ores they are virtually essential, and if carefully followed, I think, will give practically as good results as the average iodide or electrolytic assay.

Location Notice

Below is given verbatim a copy of a location notice found in California. It illustrates that in America one may know more of the rules of law than of language.

NOTIS:

i the under sined bay this day elaimd & located this spring for millen & minen purpes on the golden rull min.

elaim 5 ackers of land & runs 500 feet each way from this notis.

this spring is known es the iren Spring on cors gold gulch in town ship 9 Fresno Co. Cal.

located on the groune this 29 day of June 1888.

Practical Applications of the Specific Gravity Flask

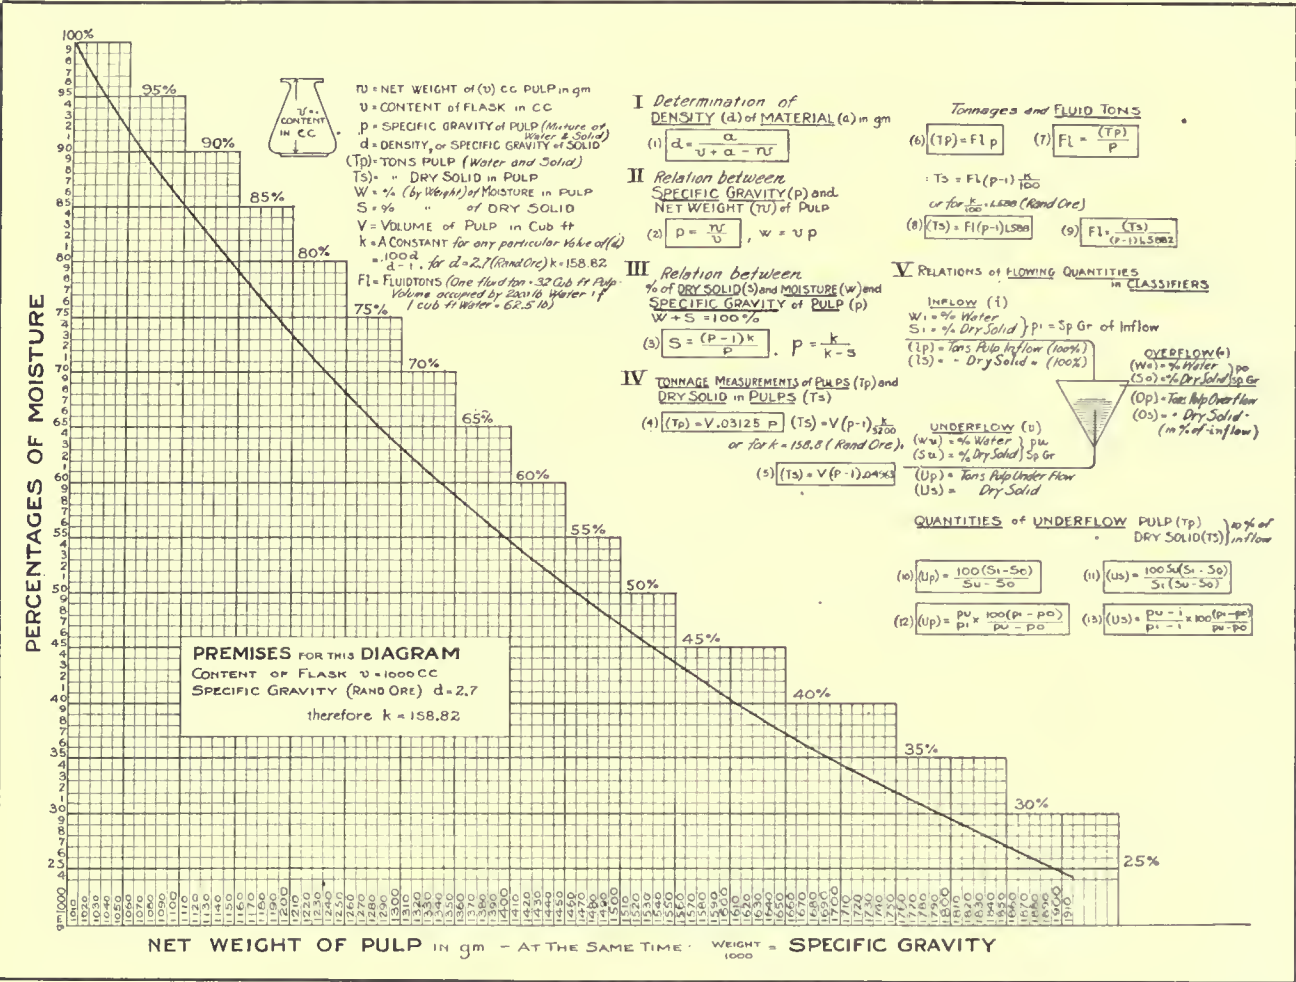

By H. STADLER

*The principal objects of these notes is to show the great practical possibilities of the specific gravity flask, which in future should prove to be one of the most useful and indispensable instruments for efficient and reliable control of the condition of mill-pulp. W. J. Sharwood's admirable article on the measurement of pulp and tailing¹ is presumably familiar to all millmen who have to deal practically with the handling of pulp. The present notes do not pretend to add much that is really novel, but I trust

added to the mark (in the suggested flask to the top), the total weight of the contents is then taken. The density is obtained by the use of formula (1). Wet material, such as mill-pulp, is preferably dried and weighed after the determination of the specific gravity of the pulp.

II. DETERMINATION OF SPECIFIC GRAVITY OF PULPS

Almost all factors determining the nature of pulps, from the millman's point of view, are governed by the specific

that some practical conclusions drawn from the above and other papers on this subject² will be welcome to those whose daily duties leave very little spare time for a thorough study of technical literature. In practice it has been found that flasks having a large mouth ground true, the ground edge to be used as the mark of capacity, are more convenient for taking fair samples than the usual glasses with a mark below the mouth. In consequence of sand adhering to the glass above the mark, the latter are more difficult to fill accurately.

I. DETERMINATION OF DENSITY (SPECIFIC GRAVITY) OF SOLIDS

If the specific gravity of the solid ore under treatment be not taken at an accepted average value, it may be determined by any well known method. For instance, if the material is dry, a known weight (in grams) of the material under examination is placed in the flask, and water

gravity of the pulp. If the metric system of weights be used, the specific gravity is at once obtained by dividing the net weight of the pulp by the volume occupied, or when a 1000-c.c. flask is used by cutting off the last three decimals of the net weight of the pulp (in grams). The specific gravity of slime pulp, in which all solids are freely suspended, may be measured by a hydrometer.

III. DETERMINATION OF PERCENTAGE (BY WEIGHT) OF DRY SOLID AND WATER

Although the specific gravity is indicative of the constitution of pulps, the percentage of dry solid or moisture conveys a more definite impression to the average mind. The usual method of determining the percentage of solids and moisture, by drying and weighing, is very troublesome, and also, as done in practice, unreliable and inaccurate. Hence methods based on specific gravity, formula (3), are vastly quicker and more convenient.

Any alteration in the composition and in the rate of flow of pulps shows itself by a marked change in the percentage of moisture and this therefore gives a reliable, sensitive, and effective control in the uniform distribution of the pulp and the regular working of classifiers. For instance, at a mine where a set of eight similar classifiers

*Extract from the Jour. Chem., Met. and Min. Soc. of South Africa, November 1911.
¹The Mining Magazine, Vol. I, Nov. and Dec. 1909.
²See F. B. Hyder's 'Specific Gravity Estimation of Pulp,' Colorado Scientific Society, Vol. IX, p. 417; and W. A. Caldecott, Jour. Chem., Met. and Min. Soc. of S. A., Vol. II, p. 375.

was fed with the same battery pulp, the moisture in the underflow of the different classifiers varied, at the same moment, from 35 to 75%, thus showing that the distribution of the pulp over the classifiers was very irregular. It is to be hoped that, with such a convenient means at hand, millmen will pay more attention to the control of individual units, as the total average always gives figures which are no help in detecting faulty work.

IV. TONNAGE MEASUREMENTS OF TOTAL PULPS (Tp) AND OF DRY SOLID IN PULPS (Ts)

Tonnage measurements of flowing quantities are generally made by running pulp for a measured time into a vessel of sufficient capacity to give fairly accurate results. Scales for weighing the large quantities collected are not practically available, and the drawing off of the water, drying and weighing of the solid portion in such quantities still less practicable. All these inconveniences are avoided by reckoning the tonnage from the volume occupied by the total pulp (in cubic feet) and its specific gravity, by formula (4) for the total pulp, and by formula (5) for the dry solid portion only.

The simplest manner to carry out these measurements is to run the pulp into a box of known capacity, large enough to take at least one minute's run of the stream. The exact time required for filling is taken by a stopwatch, the point of overflow being easily and exactly determinable. The specific gravity is determined from separate representative samples taken simultaneously, and the calculated weight of pulp or dry slime passing during the time (t in seconds) are then used to give the hourly or daily quantities. If, in all measurements, boxes of equal capacity are used, for instance, 16 cu. ft. (the volume of half a ton of water), all the constant factors may be condensed into one. For a box of the above capacity the formulae for Rand ore are:

$$\text{Tons of total pulp in 24 hours: (Tp)} = \frac{43,200p}{t}$$

$$\text{Tons of dry solid only (Ts)} = \frac{(p-1) 68609}{t}$$

Since the capacities of launders, vats, pumps, and other machines, as well as the rates of overflow of classifiers are determined by the volume of the pulp, the fluid ton of 32 cu. ft. (equal to the volume of 2000 lb. water, on the assumption that 1 cu. ft. of water weighs 62.5 lb.) is frequently used as a unit in mining work. The tonnage of pulps of known specific gravities is readily converted into fluid tons by formula (7) for the total pulp and by formula (9) for the dry solid portion.

The same method is also applicable on a large scale to the tonnage measurement of vats, provided the consistence of the pulp is not changed by drawing off water or slime (as is the case with sand-collecting and slime-settling vat), or by adding cyanide solution (as happens with slime-treatment vats). For large measurements the practical utility of this method is therefore confined to agitation or circulating-vats, and in all other cases, for lack of better methods, resort must be had to the method commonly practised, inaccurate as it is, of estimating the dry solid by the established dry weight of the settlement volume. This varies considerably with the nature and the fineness of the ore, and should therefore be checked frequently and corrected if necessary by actual test. For such tests the method I describe is suitable, as no drawing off of water nor drying is necessary.

At the Knight Central G. M. Co. the daily tonnage measurements of the mill-pulp for several years past have been regularly taken by the gravity method, which, after careful investigation, was found to give most reliable results. In addition there is the advantage that it can be carried out without waiting for settlement of the slime. After filling the first transfer tank with solution and after circulation (the whole operation taking about four hours), two samples are taken, one at the delivery pipe, representing the pulp at the bottom of the tank, and one from the upper part, to get a representative average for the whole content.

V. RELATIONS OF FLOWING QUANTITIES IN CLASSIFIERS

The relation of flowing quantities in classifiers may be calculated from the percentage of any of their components measured at the inflow, overflow, and underflow. No component can so quickly and reliably be measured as the percentage of dry solid taken with the specific gravity flask. From the percentages of dry solid so obtained, the tonnage of the total pulp underflow (as a percentage of the total pulp inflow) is calculated by formula (10) and the tonnage of dry solid underflow (as a percentage of dry solid inflow) by formula (11). In neither case is it first necessary to calculate the percentage of solid, since the flowing quantities of the underflow can directly be determined from the values of the specific gravity, by formula (12) to get the percentage of the total pulp, and by (13) to get that of the dry solid portion only. The accuracy obtainable by the specific gravity method is only limited in practice by the accuracy with which the means at our disposal determine the correct values of (1) the volumetric weight of the pulp (w), (2) the density of the solid (d), and (3) the specific gravity of the liquid (δ).

(1). *Accuracy of Volumetric Weight of Pulp.*—When using a 1000-c.c. flask an error in content or in weighing of even 10 c.c. or 10 gm. respectively, affects the specific gravity (p) of the pulp in the third decimal only. For a 1:1 pulp the error is 0.0007%, which increases with the dilution of the pulp. A variation in (p) of 0.01 in a 1:1 pulp (Rand ore) gives an absolute error of 0.74% in the calculation of the dry solid or moisture percentages, corresponding to 1.48% of the true value. With the dilution of the pulp the error increases progressively. The accuracy of the tonnage measurement of the total pulp varies as that of (p), while the tonnage of the dry portion shows an error of 2.17% which increases progressively with the dilution of the pulp. If we allow such rough work in actual mining practice, the annexed curve gives us the percentage of moisture or solid within $\frac{1}{2}$ to 1 per cent.

(2). *Accuracy of Density of Solid.*—It seems that the average density of Rand ore is, at least for individual mines, fairly steady. The constant (k) in the formula varies with the density as follows:

Density .	2.4	2.5	2.6	2.7	2.8	2.9	3.0
k	171.4	166.6	162.5	158.8	155.5	152.6	150.0

A variation from the generally accepted average density of 2.7 for Rand ore to 2.8 affects the accuracy of the specific gravity (p) in a 1:1 pulp by 0.96%, which error decreases slowly with the dilution of the pulp. The tonnage of the total pulp is affected to the same extent as (p), while the dry solid portion shows a constant error of 2.8% independently of the consistence of the pulp. For the percentage of dry solid and moisture the error is 2.06%, which increases with the dilution of the pulp. When much concentration of the pyritic portion of the ore takes place the actual specific gravity must be ascertained in each case, as an increase from 5 to 10% pyrite causes the specific gravity of the solid to vary from 2.7 to about 2.8 per cent.

(3). *Accuracy of Specific Gravity of Liquid.*—All the formulae are based on the specific gravity of pure water, but they are applicable to ordinary mixtures of cyanide solutions with enough accuracy for practical purposes, except in cases of excessively thin pulps, such as turbid water, overflow of classifying vats, etc. For exact scientific work or for much heavier liquids (sea water = 1.027) the true specific gravity (δ), corrected for temperatures, is taken into consideration in the following formulae:

$$\text{Specific gravity of pulp} = \frac{100 \delta p}{100d - S(d - \delta)}, \text{ and}$$

$$\text{Percentage of dry solid } S = \frac{100 d(p - \delta)}{p(d - \delta)}$$

In stating that the extent of the error introduced by ignoring the higher specific gravity of cyanide solutions, is not generally appreciated, Mr. Hyder was misled by erroneous information (accepted by him with the reservation "assuming this to be correct") as to the average

density of ordinary cyanide solutions. This strength does not generally exceed 0.18% for sand, 0.025% for slime, and 0.3% for black sand. I am indebted to M. T. Murray, lecturer of the South African School of Mines, for the exact determinations of the specific gravity of an ordinary cyanide solution, assaying 0.126% KCN and 0.01% alkalinity. He obtained a value of 1.0021, and from the data given above it will be seen that the small variation from the specific gravity of pure water is negligible. These results are published through the courtesy of the Mines Trial Committee though on my own responsibility.

The Colburn Mill

DENVER CORRESPONDENCE

The latest milling addition in the Cripple Creek district is the Colburn cyanide mill at the Ajax mine. The Clancy process forms the basis for the treatment system in this mill, which has been running two months and appears to be working successfully, although no actual figures as to costs and extraction can yet be given out, owing to its newness.

Statements made by local papers that \$2 ore was being treated at a profit and that the cost was 75c. per ton, have been denied by E. A. Colburn, president of the Ajax company. It is certain, however, that a good saving is being made at low cost. It is claimed that when the mill is operated at full capacity the entire cost of treatment will not exceed \$1 per ton. The control assays of the plant indicate

COLBURN MILL AND AJAX MINE, CRIPPLE CREEK, COLORADO.

a saving of 80% of the gold content of the ore. The ore treated at present is waste from the sorting-house, which would otherwise be sent to the dump, and low-grade ore obtained from development work. The ore milled averages \$4 per ton.

In the operation of this mill the ore is crushed and automatically sampled. It is then classified and crushed in cyanide solution by tube-mills, to such a fineness that only 12 to 15% remains on a 150-mesh screen. The pulp has a specific gravity of 1.3, and is agitated for 24 to 36 hours; in the meantime a current of electricity is passed through the solution. The current has a strength of 300 amperes, at 8 to 10 volts. The electrodes are of iron and graphite. The solution contains cyanide, calcium cyanamide, sulphocyanide, and potassium iodide. The chemical consumption in cyanide and potassium iodide is low, about 0.01 lb. cyanide per ton of ore treated. The only chemicals lost are those mechanically carried away by the slime, owing to defects in washing. The solutions are separated from the solids by means of a Moore filter plant. The cycle of filtering operations require 60 to 70 minutes, and the filter plant has a capacity, per cycle, of 5 lb. per square foot of filtering surface. The plant has, therefore, a large capacity. Zinc-dust precipitation is used.

The Colburn mill has a proved capacity of 250 tons per 24 hours. It is a modern mill in every respect and appears well adapted to carry on a long campaign with a minimum cost for repairs, and without danger of serious breakdowns. At present the mill will work to about half capacity, until some necessary changes have been made in the mine so as to meet the demands of the plant. A. W. Warwick is at present in charge of the plant, in behalf of the Moore Filter Co., which is exploiting the Clancy patents.

Vanadium in Southwestern Colorado

By KIRBY THOMAS

The vanadiferous sandstone deposits of San Miguel county, Colorado, have been known to the scientific world since 1899. They early attracted attention as a probably reliable source for vanadium, but only during about four years have methods of treatment been perfected which permitted their commercial utilization under the conditions of the comparatively low-grade ore and high freight costs. Small shipments of the higher-grade ore have been made intermittently to the Eastern States and to Europe for special treatment, and at the present time the Primos Chemical Co. is operating a plant at Newmire, treating about 25 tons per day.

These deposits occur in a horizontal bedded sandstone of the Jurassic period, known locally as the La Plata beds. They are found, practically continuous, as a bed or stratum in the lower sandstone bed and below a persistent and characteristic bed of dark limestone. This vanadium-bearing stratum is mainly parallel with the bedding of the sandstone, and usually has a regular bottom or floor, often marked by shale parting. This floor is from 10 to 25 ft. below the limestone. The vanadium-bearing material sometimes extends to the limestone and often expands upward, forming the 'rolls' as defined by the operators. The vanadium-bearing stratum is often a mere seam and in a short distance will expand to upward of 20 ft. in thickness. The thicker bodies are generally richer also. The La Plata beds are found continuous and undisturbed over a large area in western Colorado and Utah. They are exposed in the canyons of the San Miguel river and its tributaries and elsewhere. In the San Miguel region only, so far as is known, do these typical vanadium-bearing deposits occur. The deposits, as now disclosed by erosion, form roughly a zone, running west of north, more than fifteen miles long and two miles wide, assuming continuity through the hills or 'mesas' intervening between the exposures.

The mode of occurrence and this limitation of the vanadium-bearing stratum has suggested several theories as to its origin, a plausible theory assumes deposition contemporaneous with the containing sandstone from vanadium-charged water, presumably a river current or flow in a shallow sea. The theory of the origin is of importance as bearing on the probable continuation of the vanadium stratum beyond the outcrops.

Many drifts and openings in the vanadium stratum in the different parts of the district, several of them extending more than 100 ft. in from the outcrop, show no regular change in the character, grade, or extent of the ore. A study of the outcrops and of these workings convinces me that the vanadium stratum is practically continuous within the zone and that the outcropping vanadium deposits are not formed by surface enrichment from the evaporation of out-pouring solutions nor by localized deposition similar to fissure and contact vein deposits.

Vanadium is found in these deposits chiefly as the cementing material or matrix of the sandstone stratum, although it also permeates the sand grains sometimes to the centre, a matter of importance in the treating of the ore. The vanadium matrix is described by W. F. Hillebrand as a "crypto-crystalline aluminovanadate-potassium silicate resembling roscoelite (vanadium mica), but with the percentages of Al_2O_3 and V_2O_5 reversed. It constitutes over 25% of portions of the sandstone, and contains nearly 13% V_2O_5 ." This mineral is not easily soluble, as is evidenced by the unchanged character of the exposures.

Sufficient data to calculate the average thickness of the vanadium stratum are not available. In several places 6 to 20 ft. is exposed for several hundred feet horizontally, and in many places it is 6 to 10 in. thick, while in other places it is a mere seam or sometimes absent entirely. A safe average of the minable deposits would be $2\frac{1}{2}\%$ V_2O_5 . The ore is of a distinct olive-green and is easily sorted from the buff or yellow sandstone in mining. The shade of green indicates roughly the grade—the darker green being richer.

Metal Production and Prices in 1911

By L. VOGELSTEIN

Copper

*An examination of the admirable statistics of the Copper Producers' Association shows that while recent developments in the market may have taken the trade by surprise, they have been entirely logical. These figures, together with best obtainable foreign statistics may be tabulated as follows, all figures being in pounds of copper.

producers on their output is undoubted, but on the other hand when the large reductions in stocks are considered, together with the very flattering prospects for future consumption, it must be admitted that such increased quantities of copper as may come on the market from present producers, plus the new production which will first appear in 1912, will be taken care of readily. The total increase from

	1911.	1910.	19109.
Stock January 1.....	122,030,195	141,766,111	122,357,266
Production	1,431,938,338	1,452,122,120	1,405,403,056
	1,553,968,533	1,593,888,231	1,527,760,322

	1,464,513,838	1,471,858,036	1,385,994,211
	89,454,695	122,030,195	41,766,111

The world's production and consumption of copper last year and for three years preceding may be estimated as follows, in tons of 2240 lb. each:

both sources in 1912, as compared with 1911, may be estimated to be at least 170,000 pounds.

From all the above it would seem a fair deduction that while the recent advance has been rather spectacular, and has been accompanied by considerable speculation, and while sharp reactions may be expected, the era of low prices has been left behind and the copper industry enters the new year under more favorable auspices than since 1907. The exceptionally large deliveries of the last few months for export as well as for domestic consumption do not represent actually increased consumption, but in part a shifting of stocks from producers to consumers and speculators. A permanently higher level of prices will be reached and maintained, as soon as business conditions in this country shall have emerged from the effects of the panic, and the political unrest, the tariff agitation, and all the other causes which have deterred capital from new investments be set at rest.

	309,100,000	8,340,900,000	27.0

*Figures of consumption of all countries except United States include old metals consumed, estimated at about 10% of the above total.

STOCKS OF COPPER IN ENGLAND AND FRANCE, ACCORDING TO FOREIGN STATISTICS

December 31, 1908.....	46,227	
“ “ 1909.....	101,972	— increase, 55,745
“ “ 1910.....	72,952	— decrease, 29,020
“ “ 1911.....	47,350	— “ 25,602

Prices during the year have fluctuated as below:

	Standard spot.			Electrolytic.
	£	s.	d.	cents.
Opening	56	6	3	12.45
Highest	63	15	0	14.025
Lowest	53	1	3	11.85
Closing	63	11	3	14.025
Average	57	1	1	12.376

A considerable shrinkage of production during the last four months occurred. Just why refinery production should have declined when an increase was expected, has been a subject of considerable discussion, such decrease not having been supported by mine or smelter returns available. If imports be considered, the discrepancy widens rather than otherwise. That some restraint has been placed by large

One of the foremost American copper experts many years ago expounded the theory that copper consumption in this country runs parallel with iron consumption. Above is given an estimate of iron and copper consumption for 1911, and a comparison for the relative figures for the past twenty years. It will be noted that the average for 20 years was 27 lb. of copper per ton of pig iron. It will further be

*Statistics of production and prices in the American metal market have been printed, but the general summary prepared by L. Vogelstein & Co. has become such an institution in the metal trades that it is reproduced here with only minor abridgment.—EDITOR.

noted that aside from the panic years 1907 and 1893, the minimum copper consumption per ton of pig iron was 22.3 lb. and the maximum 30.2 lb. Indicated consumption for the year 1911 is 29.9 lb. per ton of pig iron. Such comparisons have little value for a single year on account of the change in the invisible supplies of both copper and pig iron. Over a long period of years these figures can be considered absolutely reliable.

Lead

The lead market has been without particular feature during the year just closed. Prices, with comparisons with previous years, have been as follows, in cents:

MISSOURI BRANDS, EAST ST. LOUIS				
	1911.	1910.	1909.	1908.
Opening	4.37½	4.65	4.10	3.62½

	397,814	361,827	345,255	298,672	337,340
From foreign ore and base bullion.....	89,706	108,553	102,857	97,761	76,849
Total smelter production	487,520	470,380	448,112	396,433	414,189
Consumption (estimated)	391,000	376,021	370,013	317,651	373,500

No statistics of lead are available except at the end of the year. Consequently dealers have no information intermediately, and the price changes are chiefly in sympathy with surrounding conditions. Specifically, the industry has suffered from the high price of linseed oil, which has doubtless operated to reduce consumption of white lead and still more to restrain dealers from carrying stocks. A recovery from both effects is to be expected with a return to normal conditions in 1912, and on this assumption a large and profitable year's business may be looked forward to with considerable confidence. Prices of soft Spanish lead in London, together with equivalents in U. S. currency, have been as follows:

	London, per ton, £ s. d.			Equivalent per pound, cents.
Opening	13	0	0	2.83
Highest	15	18	9	3.46
Lowest	12	15	0	2.77
Closing	15	15	0	3.42
Average	13	19	0	3.05

Present rates of duty of 2½c. per pound on pig lead and 1½c. per pound on lead in ore, will be the subject of acrimonious debate when the tariff question is reopened. However, as is the case with spelter, the local market, except sentimentally, is not likely to be affected by any readjustment of duty reasonably in prospect, as can be seen by comparing current domestic prices with those prevailing in foreign markets.

Spelter

The figures of the Geological Survey permit compilation

The consumption abroad has been phenomenal. A convention formed to control prices and regulate output in Europe was compelled to concentrate its energies on holding prices down rather than holding them up, owing to the extraordinary demand. London prices have been as follows:

	£	s.	d.
Opening	23	17	6
Highest	27	15	0
Lowest	22	17	6
Closing	26	15	0
Average	25	5	7

An examination of the various price tables herein presented shows a curious and yet logical interdependence between the different metal markets and the extent to which they sympathize with surrounding conditions, though the latter are at times at variance with specific conditions affecting the metals individually. It will be observed that each of the three preceding years closed with a rise in prices similar to that witnessed in the latter part of 1911. These movements generally have lasted into the new year and until some adverse development or natural reaction operates to check the advance. The upward movement in 1911 has been caused by an unprecedented consumption, while production increased only moderately.

As to the future, the extent which this market and in fact all the metal markets are affected by surrounding conditions has been indicated above, and these conditions will necessarily continue to play a part in fixing prices. Should present optimistic expectations in the iron and steel industry be fulfilled, there is likely to be a recurrence of high prices,

particularly during the first quarter of the year, or until present production can be supplemented by the output of works now building. Even thereafter business activity seems likely to keep demand fully up to supply for a long time to come, and in conjunction with large consumption outside this country, a fairly high level of prices is apparently assured.

Even a reduction in the present tariff rates, which are 1½¢. per pound on metallic zinc and a sliding scale rate on ores, would have no great effect either on output or prices so far as this country is concerned.

Tin

The tin market has repeated its usual variegated and turbulent history during the past year, shown by the following figures:

	London, per ton.			New York, cents per pound.
	£	s.	d.	
Opening	179	15	0	39.37½
Highest (June 9)	233	0	0	47.00
Lowest (Sept. 25)	171	0	0	37.60
Closing	205	0	0	44.77½
Average	192	7	6	42.605

The causes leading to these erratic fluctuations are still so fresh in the public mind as to make extended comment unnecessary.

Apparent consumption	111,216	107,224	103,260

One important development during the year was the adoption by the London Metal Exchange of the so-called 'standard contract' making any tin running 99¾% a good delivery instead of only Straits and Australian as heretofore, and permitting the delivery of 99% tin under penalty of £7 per ton. By reference to the foregoing table, it will be seen that the quantity of tin available for trading on the Exchange has thus been practically doubled, which it is hoped will insure a broader and more stable market. The so-called 'Syndicate' abroad which holds the bulk of the London stock (consisting almost entirely of Straits tin) has opposed the new contract, as from motives of self-interest its members were bound to do, and results of the controversy are still in doubt. The immediate future of the market is hard to gauge on this account, and while this is true, it is also true that a good demand for tin next year is seemingly assured, and whatever form of contract is used for Exchange trading, supplies will not be increased. On the contrary, the outlook is for a substantial reduction of stocks, and high prices are likely to be witnessed for a long time to come.

The United States produced 260,080 tons of asphaltic material in 1910, whereas only 228,655 tons was produced in the previous year. The greatest increase was in the production of asphaltic road oil which rose from 128,861 tons in 1909 to 159,424 short tons in 1910. This product was worth \$2,207,937, as against \$1,558,463 in 1909.

State Taxes in California

General interest in the workings of the new system of taxation in California under which public-service corporations are taxed solely for the benefit of the State, while all the taxes on real estate and personal property go to the cities and counties, warrants republication of the following summary of results of the first year under the new system, made by the State Board of Equalization:

The Board, finding that the revenues of the State from the taxes referred to, together with all other revenues not devoted to special uses, equalled and exceeded the sum of \$12,404,670, held that it was unnecessary to levy an ad valorem tax for general State purposes, and no general State tax rate was fixed. The apparent revenues of the State were:

Public service corporations taxes	\$ 8,776,095.46
Franchise taxes	1,677,745.00
	\$10,453,840.46
Less estimated delinquency.	50,000.00
	\$10,403,840.46
Inheritance taxes (less \$250,000 to school fund)	600,000.00
Corporation license taxes	807,000.00
Fees Secretary of State	280,000.00
Automobile licenses	50,000.00
Interest on State deposits	120,000.00
Tax redemptions	100,000.00
Preston, Whittier, and Sonoma collections.	180,000.00
Miscellaneous	75,000.00
Total general fund receipts	\$12,678,840.46
The following statement shows in round numbers the taxes levied upon the different classes of corporations:	
Steam railroads	\$ 3,736,000
Street railways	1,040,000
Telegraph	25,000
Telephone	400,000
Express	102,000
Car companies	89,000
Gas and electric	1,225,000
Banks	1,635,000
Insurance companies	523,000
Franchises	1,678,000
Total	\$10,453,000

ARKANSAS DIAMOND-BEARING peridotite areas were discussed at the recent meeting of the Geological Society of America by L. C. Glenn. He offered evidence of the circulation of presumably thermal waters about the margin of the original pipe described by J. C. Branner. A supposed extension of the peridotite area proves to consist of disintegrated peridotite mixed intimately with well-rounded quartz sand and occasional water-worn chert pebbles and was evidently water-laid. Indications of the age of this material narrow the period within which the extrusion of the peridotite must have occurred. Any information bearing on the origin of diamonds in nature is welcome since, despite the large amount of study devoted to the subject, the problem is far from being solved.

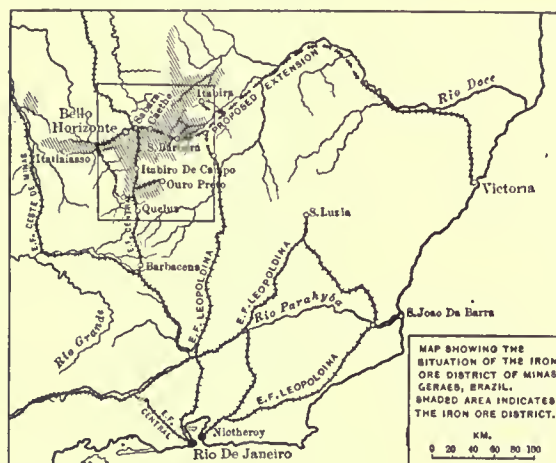

IN EXCAVATING for cellars at any place it is good policy to run a level line over the course for the proposed sewer. Then if the land slopes locally to the east, but it is desirable to conduct the sewage to the west, the cellars can be excavated to only a shallow depth at the eastern end and the concrete built up two or three feet above the ground. This will save several feet of digging along the entire line of sewers, and is in contrast to the predicament which sometimes arises when it is decided to put sewers in where the cellars were all dug equally deep but are at various elevations.

Hematite Ores of Brazil

By C. K. LEITH and E. C. HARDER

*The iron ores of the Minas Geraes district of Brazil are more nearly like the Lake Superior iron ores in their types, geologic association, richness, and quantity than anything yet discovered. The situation of the district with reference to the coast appears on the accompanying sketch map. The distance from the coast is 300 to 400 miles.

The important ores in this district are massive hematite and jacutinga.¹ Secondary concentration resulting from the impurities has enriched much of the jacutinga ore but has not been sufficient to form ore deposits from ordinary iron formation or itabirite² as has been the case in the Lake Superior district. Brazilian ores are associated with vast quantities of residual or transported fragmental ores, usually of a somewhat lower grade than the bedded ores, and therefore not to be immediately utilized, but still constituting enormous fair-grade deposits for the future. Parts of this ore not cemented are locally as rich as the massive ores and will be early utilized. Because of glaciation, the coun-

MAP SHOWING THE SITUATION OF THE IRON ORE DISTRICT OF MINAS GERAES, BRAZIL. SHADED AREA INDICATES THE IRON ORE DISTRICT.

terparts of the fragmental ores are not abundant in the Lake Superior region.

Estimates of tonnage for the region as a whole would be premature with the present state of knowledge, but it is certain that the estimate of O. A. Derby for the International Congress of Geologists, of two billion tons for the district, is conservative. Of the high-grade massive hematite and jacutinga ranging from 63 to 69% iron, the tonnage is probably not far short of the total reserve of available ores in the Lake Superior region today. Individual deposits contain several hundred million tons.

The rich and important Brazilian massive hematite and jacutinga ores seem to be the result of direct sedimentary deposition, as more or less hydrated hematites, without much

impurity, which have since been merely dehydrated and have required no extensive secondary enrichment to make rich ores out of them. Counterparts of these in the Lake Superior region are relatively insignificant, the nearest being the specular hematites of the upper parts of the Negaunee formation in the Marquette district of Michigan, and the hard blue hematite of the Soudan iron formation at the Minnesota mine in the Vermilion district of Minnesota, but both of these have suffered secondary concentration. In each of the sedimentary iron formations of Lake Superior there are certain layers originally richer than others which have required less secondary enrichment than others to make iron ores from them, but in all of them more or less conspicuous secondary concentration has been necessary to make ores even from the richer layers. Furthermore, the evidence is good in the Lake Superior region that the original iron formation was deposited dominantly as ferrous compounds (iron silicate and carbonate), which have since been oxidized, rather than being deposited directly as ferrie oxide.

The porous portions of the jacutinga beds, the leached carbonates, and the replacement deposits of manganiferous iron ore of the Brazilian field, represent a secondary enrichment essentially by the leaching of carbonate and silica and by oxidation and local transportation of the iron, this secondary concentration being similar in all essential respects to that which has produced the Lake Superior hematites. In porosity and slumping, due to leaching of carbonate and silica, the ores are similar in appearance to those in the Lake Superior region. They are on the whole much less hydrous and are more crystalline. In the Brazilian field the leaching of silica is less extensive, however, than in the Lake Superior district, for the reason that the silica to be leached is largely in the form of coarse quartz sand and locally recrystallized under the influence of dynamic metamorphism and intrusion, each individual presenting relatively small surface in proportion to its mass, and therefore being with difficulty dissolved by the percolating waters. In the Lake Superior iron formation the silica is in the form of fine chert presenting large areas in proportion to mass and being leached much more readily. The fact that so little of the silica in the itabirite has been dissolved and transported may be partly due to this. The concentration of the jacutinga is apparently largely due to the leaching of carbonate.

The fragmental ores formed by ordinary processes of weathering and erosion probably were at one time present in the Lake Superior region in enormous quantities as they are now in Brazil, but erosion represented by the pre-Cambrian unconformities and glaciation has removed them. The only counterparts of these ores in the Lake Superior region to be found now are in conglomerates at the base of the series resting on iron formations.

It thus appears that each of the principal classes of Brazilian iron ores has its counterpart in the Lake Superior region and that much the same processes of ore concentration have been active in both districts, but that the relative effectiveness of these processes and their results have differed in the two districts. In the Lake Superior district primary sedimentation was not sufficient to produce iron ore. Important secondary concentration was the essential controlling factor. In the Brazil region primary sedimentation produced abundant and rich ores; secondary concentration was a minor factor, only locally important in developing ores.

The study of the origin of sedimentary iron ores has been directed toward their secondary alteration to such an extent that little progress has been made in ascertaining precisely the topographic, climatic, or other conditions controlling the deposition of sediments rich in iron. The proof that there are in Brazil beds of iron oxide running up to 2000 ft. in thickness, containing 65% or more of metallic iron, which were deposited substantially in this form, brings investigators squarely against a problem of sedimentation which requires for its solution much more extensive knowledge of the factors that have influenced sedimentation of iron-bearing beds in their variable occurrence over the world.

*Abstract from *Economic Geology*.

¹The term jacutinga is also applied to soft laminated itabirite. In this paper, however, it is not used in this sense. The term itabirite is frequently applied to the iron formation as a whole, including the ores, but in this paper it is used only for the ferruginous sandy rock which forms the bulk of the iron formation and with which the ores are associated.

²This name was originally proposed by Eschwege, in 1822 ('Geognostisches Gemälde von Brasilien') for the massive pure iron ore of which the peak of Itabira do Campo, among others, is composed, and which is associated with a schistose rock composed of granular quartz and scaly hematite which he discriminated as iron-mica schist (*Eisenglimmerschiefer*). By common usage the name has come to be applied to the latter rock, and it is only in this sense that its retention can be justified as a convenient term for a rock type that would otherwise have to be designated by an awkward and misleading descriptive name. Through variation in the relative proportions of the constituent elements this type of rock grades off on one side to a purely quartzose and on the other side to purely hematitic phase. The phases sufficiently rich in iron to be commercially valuable may be conveniently designated as itabirite ores.

Physiography of the East African Plateau

By GEORGE L. COLLIE

*Four physiographic regions may be recognized in British East Africa: (1) the coastal plain; (2) the foot plateau; (3) the gneiss plateau; (4) the lava plateau, which includes within its boundaries the great Rift valley. The coastal plain is generally but two or three miles wide. It is composed of recent coral rock, and it is a true degradation plain; the agent is probably marine erosion. Rising rather abruptly from the coastal plain is the great plateau which extends to the basin of Victoria Nyanza. The frontal portion, called by Gregory the foot plateau, is underlain by sedimentaries of Mesozoic age. The main portion of the plateau is gneiss, but toward its western border there have been great extravasations of lava, which have completely covered the original gneiss surfaces over a belt 100 miles wide and extending north and south indefinitely. The lava flows are connected with the rifting processes that have formed the Rift valley. The underlying rocks have some bearing upon the minor features of the different regions, but this is a matter of detail. The plateau as a whole from ocean to the Victoria Nyanza basin should be considered as a unit in its large aspects. The plateau is a very ancient feature; it has been thoroughly peneplained, though great residual masses of gneiss remain, especially in the region between Voi and Kiu. These mound rocks in some cases rise to the dignity of mountain ranges. The most remarkable feature of the plateau is the constant, uniform rise of the peneplained surface from sea-level to a height of nearly 10,000 ft. at the Man or Western escarpment of the Rift valley. The plateau surface is really a great beveled slope which rises on the average about 20 ft. to the mile for 500 miles. The plateau is typical of those that lie in the monsoon region, in that only the higher portions and those that lie near the sea-level are being acted upon by normal erosion. The intermediate and by far the greater area is being degraded by deflation and sheet-flood erosion chiefly. There are two brief and widely separated rainy seasons. The conditions are such that, in the main, there is a large intake of ground water and relatively little runoff, and hence little dissection. In the interim between rainy seasons the ground becomes parched and dry, so that deflation becomes of importance and offsets dissection. The plateau confirms the truth of observations made in South Africa and elsewhere that one type of peneplanation may go on at any altitude above sea-level. This type of peneplanation does not require desert conditions, as is sometimes said. Thirty inches of water falls annually over much of this plateau, but this does not require monsoon conditions in which rainfall is concentrated in widely separated rainy seasons with arid or semi-arid conditions between.

Dunderland Iron Mines

The Dunderland Iron Ore Co. was formed ten years ago to exploit an extensive deposit of low-grade iron ore in Norway near the port of Mo on the Ranen fjord. The company has spent immense sums of money trying to beneficiate the deposit by dry-crushing and magnetic separation, but it has been a failure so far; thus forming a strong contrast to the great iron-ore industries of central and northern Sweden and Lapland. The scheme was pushed here by Sir Joseph Lawrence, who is also well known as the introducer of the linotype in England. It had the active support of many leading English and Welsh ironmasters. The metallurgical outfit was constructed on an immense scale with Edison giant rolls and magnetic plant. Any amount of mechanical and electrical troubles cropped up, and finally the plant had to be abandoned. Two years ago the Ulrich wet magnetic concentrator was recommended. This process emanates from Krupp's. Henry Louis, the consulting engineer, and D. A. Brenner, the manager, tried

it on a small scale, and subsequently a plant to treat 40 tons per day was sent to the mine for practical demonstration. It is stated that this has given good results, so plans have been prepared for a plant to treat 200,000 tons per year, capable of being easily duplicated. Arrangements are also being made for the erection of a hydro-electric station for the provision of current and power. Further progress is prevented at present by the difficulty of raising the necessary new capital. The company is so overwhelmed with shares and debts that any new financial arrangement must give great anxiety to the new subscribers and the old creditors. The present position of the company is that there are £200,000 of prior lien bonds, £648,000 debentures and funded debenture interest; of share capital, there is £1,000,000 in preference shares and a similar amount of ordinary shares.

Electrolytic Recovery of Zinc

By THOMAS SAMMONS

A new process for the electrolytic recovery of zinc has been successfully worked out by Chitaro Yoshida, the proprietor of a copper mine in Iwashiro Province, Japan. The zinc ore is dissolved in the electrolyte, and from this liquid the zinc is precipitated by electrolysis. The process is simple, but several obstacles have been found. For instance, the presence of a small quantity of copper, antimony, or arsenic is enough to render the process futile. One of the defects of the process heretofore has been the spongy form in which the zinc adhered to the cathode. To prevent this, carbon was tried instead of lead in the anode. The carbon was coarse and dissolved in the sulphate of zinc, and the zinc which gathered on the cathode was then found to be refined to a degree rarely surpassed by the imported metal. During 1910 Japan exported 24,747 tons of zinc, valued at \$383,485, and imported 11,581 tons. It is believed that a new industry will be built up in Japan as a result of this new process.—*Consular Report.*

Building Stone From Slag

By GEORGE NICOLAS IFFT

The manufacture of building stone from smelter and blast-furnace slag is an industry of considerable importance in Germany, and is carried on to a greater or lesser extent at nearly all such plants. The process is not patented and is very simple in detail. Practically all blast-furnace and smelter slag is suitable for stone-making. Slag for this purpose must, however, be in a granulated state. After it has been allowed to harden it is unsuitable. All attempts to utilize slag that has been crushed or ground, after having once hardened, have failed to result in a solid stone. The slag is granulated by the addition of water as it flows hot from oven or furnace. It is then mixed with lime—pulverized slaked lime or milk of lime—in the proportion of 7 to 10 parts of slag to 1 of lime, according to the nature of the slag, and while moist in this condition is subjected to pressure in molds of the desired size and shape. A special type of press, with pressure power of 22,000 to 50,000 kg. (kilo = 2.2 lb.), is used. An improved type of press of this kind costs about \$3000. Practically any form of power may be used and any desired shape of mold. The granulated slag after being thoroughly mixed with the required proportion of lime, is allowed to stand one hour before being put through the press. After being pressed, the stones are stacked in the open air, where, after three or four weeks, according to the weather, they are ready for use. Under low temperature they harden slowly. If subjected to frost before thoroughly hardened, they are crumbled and destroyed. Operations may, however, be continued in the winter, the stones being hardened in steam-heated drying-rooms. These stones grow constantly harder with time, and after several years show a resistance of 100 kg. per square centimetre.—*Daily Consular Reports.*

*Abstract of paper read before the Geological Society of America.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Mill and Cyanide Plant Records

The Editor:

Sir—The fact that the unmarranged material was submitted for consideration only, and was marked “not for publication”, exonerates me from any blame because ‘Mill and Cyanide Plant Records’ has appeared in your issue of December 2 in a form that makes it almost unintelligible, and of little practical value.

The matter enclosed in squares and representing (1) Mill records, (2) Amalgam records, (5) and (5a) Filter and press records, (9) Bullion Book, (11) Assay Book, and (12) Determinations, are headings for each page of the book or sheet in question, the last column in each case being left for a space for remarks, for example:

FILTER-PRESS RECORDS

Date	Shift	Press No.	From		Filling		Washing		Discharging		Remarks
			Charge No.	Vat No.	from	till	from	till	from	till	

The sand and slime plant records should be arranged in the same way but “totals & averages” refers, naturally, to the results of the work for the period, and not to the clean-up; and “extraction %” should take the place of “extraction, percentage, per ton, \$”, as below:

SLIME-PLANT RECORD BOOK

Date filtered	Charge No.	Vat. No.	Tons	Assay		Extraction		Amount called for by assays
				Heads	Tails	per ton	%	
TOTALS & AVERAGES								

Clean-up No.
.....19....

.....oz. bullion of
average fineness
= oz. fine gold.

Remarks:

The “summary of treatment results”, abridged, should appear as follows:

SUMMARY OF TREATMENT RESULTS

for the weeks ending 19....
Tonnage.....

	Oz.	\$ per ton	%
Recovered by amalgamation			
“ cyanidation			
Total recovery			
Value of residue			
Value of ore milled.....			

.....
..... 19.... Metallurgist.

The “leaching vat records” are very nearly correctly arranged, the whole sheet being used for a charge, but entries of “tons” and “%” of solution applied should be allowed the whole of the right-hand side of the sheet, since such entries are generally numerous, corresponding to the number and cyanide strength of washes given forming the treatment.

A. W. ALLEN.

London, December 16, 1911.

[We regret greatly the misunderstanding and errors in printing Mr. Allen’s article. The manuscript was received by us in the regular course in a form we assumed to be satisfactory to him. We are, of course, glad to make the correction.—EDITOR.]

‘Dig to the Depths’

The Editor:

Sir—The enclosed editorial is from Nevada’s leading newspaper. Verily, “distance lends enchantment.” “Sink the shaft to great depths, regardless of the fact that the surface of the lode never gave the slightest indications, and does not now, of ever becoming a mine. Squander a large amount of money, instead of the small amounts now being squandered, MAKE ore exist where it never has and where

the indications are it never will, but ABOVE ALL PROSECUTE THE WILD-CATTER, who deceives people regarding the mines of our glorious state!!!!” The mine referred to is the Wedekind. It has never been and never will be a mine, and is now, as it has in the past, absorbing

hundreds of dollars for every little one-pound specimen of lead-silver ore found in its stringers.

A SUBSCRIBER.

Elko, Nevada, December 29, 1911.

[The advisability of systematic development instead of “woodpeckering the surface,” is something about which all agree, but the editorial in question, quoted below, is an excellent example of the misinformation upon which it is well not to base development.—EDITOR.]

“Heretofore the error in developing the resources of the great dyke that extends to the northward from Reno has been in woodpeckering the surface over a great area and at no place attaining to any consequential depth.

“If the money that has been expended in sinking hundreds of shallow holes had been devoted, through community of interest, in sending down several bores to great depth, Reno would now doubtless be a big, bustling, prosperous mining camp.

“It is true of at least one property, the Wedekind, that the water level brings a bulge to the zone of mineralization,

with an accompanying lowering in values, but that would naturally occur at the point where the percolation of waters bringing the secondary enrichment forces the walls asunder and permits the occupation of the crevice with waste.

"At greater depth it will almost undoubtedly be found that the vein contracts and grows heavier with value, not in lead, but in the nobler metals.

"The big dyke must be worked in different fashion from narrow ledges of pure silica, where faults and slips are the only imperiling features. This granite walled fissure, two miles in width, naturally contains its surface ores but as the cake contains its raisins, in widely separated lenses, and the wider the dyke the farther apart the heavy enrichments.

"But at the greater depths there is almost certain to be concentration. The granites will be found to have approached and the many lenses to have concentrated into one definite, well walled vein.

"Thus far the operators at Wedekind have but reached, not the cream, but the surface scum.

"To the depths, gentlemen: to the depths, and may nature well reward you!"

Tanganyika Concessions, Ltd.

The Editor:

Sir—The articles in your issue of January 20, 'Mining in the Belgian Congo in 1911,' by Sidney H. Ball, and 'Claims of the Tanganyika Concessions,' from your London correspondent, indicate the great interest being taken in this Central African mining enterprise.

This work is being done by the proprietary company, the Union Minière du Haut-Katanga, a corporation with headquarters in Brussels and in which the Tanganyika Concessions is but a minority shareholder. At the Union Minière meeting last month, M. Jadot, the director, gave estimates of tonnage exposed in ten of the company's claims, aggregating 10,000,000 tons, and his statement has been taken as if new and important, when, in fact, he was but repeating estimates made five or six years ago based upon a few cross-cuts run for the sole and special purpose of "establishing to the satisfaction of the Katanga special committee that the mines were workable," and without the slightest intention of putting ore 'in sight' to be measured. The figures have a meaning about like that which would attach to the publication now of some one's estimate ten or twenty years ago of ore then proved in Butte, Montana, or along the Mother Lode of California—districts, by the way, in which mining is conducted on the assumption that there is ample ore in the ground for a continuance of business and guiltless of any attempt to "estimate tonnage." However, your London correspondent, referring to the Tanganyika meeting, says: "This leads me to the most interesting of all the statements made at the recent meeting, a remark really quite incidental, to the effect that Mr. Frecheville had vouched for 1,800,000 tons of 12% ore." At both the Tanganyika and Union Minière meetings those figures were clearly given as Mr. Frecheville's estimates, made five years ago, of the ore in the Kambove workings alone; additional estimates being also as clearly stated for other claims he inspected, and at length the idea seems to be gradually dawning that his inspection had nothing whatever to do with the operations of the mine, but was connected entirely with some private share-dealing proposals. At the same meeting Robert Williams much more pertinently said, "In fact, it seems to me that what we are calling mines are simply the outcrops of a belt of copper which runs from one end of the country to the other."

The toy furnace now treating a little over 100 tons of ore daily from the Star of the Congo mine is on the Lubumbashi river ten or twelve miles southeast from the extreme southeastern mine of the belt, which thence extends northwest nearly two hundred miles, and it is fed by a crooked, three-party railway meandering around 1800 miles up from Beira on the Indian ocean. It is in no sense a properly situated and constructed central reduction works with suitable railway transport, and should be taken only

for what it really is—a testing plant. The important works will come in due time.

By due time is meant the following: In Katanga, as has been pointed out from the beginning, there are two classes of oxidized copper ores, one that can be turned readily into copper by blast-furnaces, and another not adapted to such treatment. Both exist in really enormous quantities along the belt, and constructive engineers who were employed to build up the enterprise openly and admittedly confined their attentions to the first kind and relegated the other to the future; while the wiseacres, the learned and technical critics, both inside and outside the lines, have made the second prominent and slighted the first. Now anyone, no matter who or what he be, stating that it is either difficult or very expensive to get copper from either class of ore, is speaking from ignorance, not from knowledge. He means that it is very difficult or very expensive to make copper by the processes with which he is acquainted, and assumes that ends the matter. It does not end it. For over twenty years past there have been no large deposits of good-grade oxidized copper ore available for treatment, and therefore, of necessity, attention has been forced to confine itself to the working of sulphide ores, with the result that a surplus of copper is being made from materials not long ago considered valueless. Suppose conditions had been reversed, who will assume that methods would not have been worked out to efficiently and economically extract copper from high-grade, silicious carbonate? That is exactly what will have to be done in Katanga under superb local conditions for working, and some one will some day, may any day in fact, do it; and it is futile to ignore the consequences. Further, it is known that success in copper enterprises has come from cheapened transport and the outlay of vast sums of money in huge plants to handle economically a great tonnage. The mechanical improvements are wonderful, but when it is understood that, where concentration is used, from 25 to 40% of the metallic content is lost, the metallurgical results are not quite such as to recommend any 'great specialists' wedded to such method to people with chemical and metallurgical problems to solve.

Tanganyika Concessions, Ltd., has grown into a holding company, upon which has devolved the work of opening up South Central Africa, and its great expenditure and large financial deals have been in the railroad and not on the mining side of its business. Its shares are the 'market counters' through which it gets money; when they are high, work goes ahead rapidly; when they are low, some things lie idle. Lately they have fallen heavily, and hence are written and talked about a lot; but they have fallen several times in ten years, only to rise again, and that is why they are attractive. Men of speculative tendencies so like to gamble that every community has to restrain them by law from taking certain chances, and 'Tanks' constitute a lawful gamble. Whether or not this is a legitimate basis for a great mining company to finance upon is a matter of individual opinion, but it must be conceded that in all great industrial undertakings it is 'the other people's money' that is used, and the methods of securing this vary with circumstances. For instance, to get it in this country it has been necessary to go to what is termed 'the interests', 'the system'. Wall Street is not in disrepute, though many people have a notion there has been too frequently an excessive 'rake-off to the house' and sometimes even a 'brace game'. When rich placer ground was found in Alaska every outfitter, transport man, hotel proprietor, real estate dealer, and handy chap from Juneau to San Diego trumpeted the glad tidings, in the hope that the resulting stampede would fill his pockets with other people's money, and it happened just so in many cases. That Tanganyika Concessions, Ltd., has succeeded also is clear from Mr. Ball's description of Elizabethville. To read of that town increasing its white population from 100 to 1500 in a year, with thirteen miles of boulevards laid out, cafés surrounding the 'Place Royale', and town lots bringing from \$9000 to \$12,000, is bewildering to one who, a few years ago, by forced marches with a few picked carriers on starva-

tion rations, reached Kipushi, one day from the Star of the Congo, and could go no further, as not another pound of native food could be had.

This mining company, Tanganyika Concessions, Ltd., has done more in ten years to open darkest places in Africa to the world than have all other agencies combined during the centuries, and back of it all is a charming Scotch gentleman from Aberdeen, Mr. Robert Williams.

J. R. FARRELL.

San Francisco, January 22.

Heating Cyanide Solutions

The Editor:

Sir—In your issue of January 6, under heading of 'Heating Solutions,' Alfred James in his 'Progress in Cyanidation of Gold and Silver Ores During 1911', expressed a desire for data on benefit of heat on extraction. The following tables of comparison, showing extraction on Belmont ore, with different degrees of temperature, may be of interest. The benefit shown has been borne out to our entire satisfaction in practice.

I. ORE Au 0.05 oz., Ag 18.2 oz., TOTAL VALUE \$10.15

Agitator.	Agitation,		Tailing.		Val.
	Hours.	Temp.	Au. oz.	Ag. oz.	
Belmont	60	Cold 60°	0.015	3.1	\$1.86
"	60	Warm 90°	0.01	1.7	1.06
Pachuca	60	Cold 60°	0.02	3.8	2.32
"	60	Warm 90°	0.015	2.1	1.36
Bottle	60	Cold 64°	0.02	3.4	2.12
"	60	87°	0.01	2.5	1.49
"	60	109°	0.01	1.7	1.06

II. ORE Au 0.05 oz., Ag 20.6 oz., TOTAL VALUE \$11.30

Agitator.	Agitation,		Tailing.		Val.
	Hours.	Temp.	Au. oz.	Ag. oz.	
Belmont	48	+ 90°	No sample taken.		
Pachuca	48	+ 90°	0.015	2.6	\$1.61
"	48	60°	0.02	4.5	2.67
Belmont	69	+ 90°	0.01	1.7	1.06
Pachuca	69	+ 90°	0.015	2.1	1.36
"	69	60°	0.02	3.8	2.32

Material agitated in each of the above tests was taken from collectors and contained the gold and silver remaining after concentration and that dissolved in crushing and conveying at head of mill.

To maintain a heat of 90° in the agitators, boilers are run two 8-hr. shifts during summer and three 8-hr. shifts during winter, being fired with crude oil at a cost of \$2.05 per barrel at the mill, making cost per ton of ore treated \$0.161 for past nine months. Degrees of heat are marked + 90 to show they were kept as near 90° as possible, varying from 90 to 95 degrees.

A. H. JONES.

Tonopah, Nevada, January 17.

[This note on experience at the Belmont mill, courteously furnished by Mr. Jones, should stimulate others to relate their experience, as the line of investigation is one along which accurate data are badly needed.—EDITOR.]

The Way of a Man With a Mine

The Editor:

Sir—Your issue of the *Press* dated December 16 arrived here today, and, as usual, its contents were avidly devoured. Unfortunately, the frosting of one article, very satisfactory in itself, failed of ready digestion. I refer to the quotation and the origin thereof given by T. A. Rickard, at the conclusion of his very able article. The limitations of an itinerant library fail to support a somewhat treacherous memory, but at the risk of an accusation of pseudo-sapiency, I venture the theory that the distinguished editor of *The Mining Magazine* has confused the 'Tale of the Heathen Chinese' with 'Certain Maxims of Hafiz' by one R. Kipling.

CHAS. S. HALEY.

Forks of Salmon, Cal., December 20, 1911.

The Editor:

Sir—Permit me to protest against Mr. Rickard's crediting Bret Harte with the excerpt from the 'Maxims of Hafiz'. Probably no one has more admiration for the genius of the late Mr. Harte than I. Furthermore, I will admit that Mr. Kipling seems to have gone rather to seed of late, but do let justice be done, even though the ceiling fall.

STANLEY C. SEARS.

Guanaceví, Durango, Mexico, December 21, 1911.

[Our correspondents' letters illustrate the fallibility of memory as applied to quotations. In Kipling's 'Departmental Ditties' one of the 'Certain Maxims of Hafiz' given is:

"The ways of 'a man with a maid be strange, yet simple and tame,

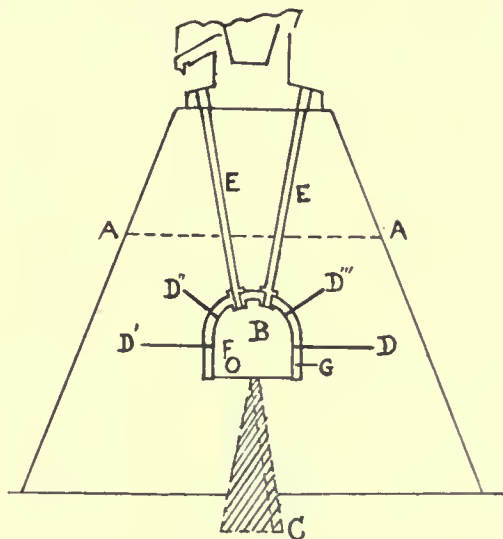

To the ways of a man with a horse, when selling or racing the same."

The version of this given by Mr. Rickard undoubtedly represents Bret Harte's sentiments in regard to mining, even though he did not chance to express them in precisely that form.—EDITOR.]

Stamp-Battery Cam-Shafts

The Editor:

Sir—In the Discussion columns of your issue of January 13, under 'Stamp-Battery Cam-Shafts', an error has been made in saying that I proposed a bearing between each stamp. This should be a description of the City Deep cam-shaft bearings, a part of the Leshinger patent. To explain what I meant by "placing the line shaft immediately under the cam-shaft", the sketch will make clear.

BATTERY FOUNDATION PLAN.

Through the centre of the concrete foundations is placed a cast-iron tube about 2 ft. in diameter, *BG*. Into this casting are screwed the pipes *E E'* to receive the mortar bolts. If these bolts are 1½-in. diam., the pipes are 2 in.; if 2-in. bolts, the pipes are 2½ in. in diameter. The line-shaft boxes *F* are also placed in this hollow, so that the cam-shaft is vertically above. It may be objected by some that the bearings cannot be oiled without stopping the mill. This can be overcome by a connection with this pipe at right angles in the centre of the foundation, so that one could crawl in and examine all the boxes and bolts, and replace those that are broken. The projections *DD' D''D'''* are projections from the casting for reinforcement purposes. The mortar bolts may be replaced, if broken, by lowering into the hole *C*, which may be made of the same size pipe as *EE'*. The bolts at the back of the mortar may be taken out from the top. *AA* is the level of the sole-plate for the battery posts. This will make my meaning clear, I believe.

ALGERNON DEL MAR.

South Pasadena, January 15.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

A GOOD cement for chemical apparatus is made of 20 parts gutta percha, 10 parts of yellow wax, and 30 parts of shellac, melted together.

FOR the purpose of improving aluminium, without increasing its specific gravity, it is mixed with 4 to 7% of phosphorus, whereby the density, tenacity, and especially the toughness are said to be enhanced.

LEAF BRASS is also called Dutch gold, or imitation gold-leaf. It is made of copper, 77.75 to 84.5 parts, zinc 15.5 to 22.25. Its color is pale or bright yellow or greenish, according to the proportions of the metals. It has an unusual degree of ductility.

IN order to impart to aluminum the appearance of mat silver, plunge the article into a hot bath composed of a 10% solution of caustic soda saturated with kitchen salt. Leave it in the bath for 15 to 20 seconds, then wash and brush; put back into the bath for half a minute, wash anew and dry in sawdust.

HAMMER-DRILLS are used near Atlin, British Columbia, in breaking lumps of frozen gravel. The bit used is sharpened as is a moil, and cuts into the clay and gravel quickly. The vibration of the drill seems to shatter the material and, by prying a little, lumps as much as ten feet in diameter can be broken.

THE eight-hour law in California applies to all persons employed in underground mines or workings, or who are employed in smelters and other institutions for the reduction or refining of ores or metals. The State Supreme Court has held that the latter phrase includes quartz mills, and hence that the statute is applicable to millmen.

TO FACE a cast-iron pulley with leather, apply acetic acid to the face of the pulley with a brush, which will roughen it by rusting, and then when dry apply a cement made of 1 lb. of fish glue and $\frac{1}{2}$ lb. of common glue, melted in a mixture of alcohol and water. The leather should be placed on the pulley and dried under pressure.

ROASTING and magnetic concentration is the favorite process for treatment of complex zinc-iron sulphides. In the Wisconsin district many of the individual mines support cheap plants of this sort which permit the production of a sufficiently high-grade product to bring about competitive bidding for the concentrate. An electrostatic plant was built and treated mixed ores till burned. In this plant a merchantable product was made from the iron sulphide which in ordinary treatment is lost.

SHAKING PLATES have been hitherto generally adopted on the Rand. At the Randfontein Mines it has been shown by experiment that movement is not at all essential nor does it contribute in any way to increased efficiency. Stationary plates have therefore been adopted at Randfontein and elsewhere, and in general there is a tendency, in addition, to materially reduce the total area of the plates from that previously in use. No loss of efficiency has yet been noted by reason of this reduction, while there has been some economy.

AN excellent cement for porcelain and stoneware is obtained by mixing 20 parts of fish glue with an equal weight of crystallizable acetic acid and evaporating the mixture carefully to a syrupy consistency so that it forms a gelatinous mass on cooling. For use, the cement thus obtained is made liquid again by heating and applied to

the fracture with a brush. The pieces should now be pressed firmly together, by winding a twine tightly around them, until the cement has hardened.

BUNKER COAL is usually taken on by merchant steamers at both ends of a trip. The Pacific Mail boats, however, frequently carry enough coal from Japan for the round trip, and the White Star line is about to adopt the practice of taking on board sufficient coal at New York for a round trip. Other lines of transatlantic ships are to do likewise, mainly because domestic bunker coal averages higher in quality than most of the bunker coal of western Europe and is supplied at low cost, as compared with foreign coal of prime steaming grades.

DURING the last fiscal year 23,272 square miles of the United States was topographically surveyed by the U. S. Geological Survey and 6460 sq. mi. revised or re-surveyed, making a total of 29,732 sq. mi. About 37% of the entire United States, exclusive of Alaska, has now been thus surveyed. These surveys are represented by more than 2000 separate sheets. The price of the standard topographic map sheet is 5c. each, or \$3 per hundred. Index maps of the various States showing the area covered by each separate sheet will be furnished free on application to the Director of the Survey, Washington, D. C.

THE ordinary concentrated sulphuric acid contains 95% of acid, or between 35 and 36 times normal. Any acid stronger than this must be made by adding fuming sulphuric acid to the ordinary acid. Strong sulphuric acid and the fuming acid absorb moisture very rapidly from the air, and thus become diluted in a short time. In order to overcome this difficulty the following apparatus may be used to weigh the acid for analysis: A small pipette similar to a medicine dropper was inserted in one hole of a two-holed rubber stopper and the other end of the hole plugged with a glass rod. In the other hole was inserted a glass rod bent at the upper end so that the whole arrangement could be hung on the arm of a balance. The weight of the apparatus was then found. In using the apparatus the pipette was removed from the stopper, filled with acid, quickly dried, put back into the stopper, and weighed. The whole apparatus was then carefully washed with water, the washings and acid diluted, titrated with standard alkali, and the result calculated for the strength of the acid in per cent of SO_4 . The strengths of the ordinary concentrated acid and the fuming acid were determined in this way, and the percentage of each necessary to form the required mixture calculated.

TANTALUM ORE is not in demand in the United States; so far as known the only firm reducing tantalum from its ores is Siemens & Halske, A.-G., of Charlottenburg, Germany, which draws tantalum wire, which is sold to incandescent electric-lamp manufacturers, and sells metal to firms which manufacture surgical and dentists' instruments and pens. During 1910 the firms forming the National Electric Lamp Association used 1,500,000 metres, equivalent to 4,921,250 ft., or more than 932 miles, of tantalum wire for filaments in incandescent lamps. The wire was of various sizes, and was valued at \$13,000. The weight is not known, but was probably less than 100 lb. It seems likely that the tantalum used for lamps in the rest of the world is not greatly larger in quantity than that used in the United States. The quantity used in instruments and pens is not large, and probably the whole output of metallic tantalum does not exceed a short ton per year. It is made from Australian and American ores. Tantalum minerals free from columbium and other objectionable elements are found in considerable quantity in the Greenbushes and Pilbara districts of Western Australia, but the American tantalum minerals are mostly columbites carrying large percentage of columbium, so that at the same price Australian tantalum minerals are preferable. The latter are stibiotantalite (tantarate of antimony), tantalite (iron tantarate), and manganotantalite (tantarate of manganese).

BULAWAYO, SOUTHERN RHODESIA

CHARTERLAND DEVELOPMENTS.—RHODESIAN GOLD PRODUCTION.—SEARCH FOR LABOR.—SLEEPING SICKNESS CLOSES NEAREST SUPPLY.—PLAN TO IMPORT WORKERS FROM LIBERIA.

The popular impression outside of Rhodesia appears to be that mining in Charterland is at a standstill and that the short-lived boom of 1909-1910 has left Rhodesia a mining country that was. It is quite true that things in Matabeleland and Mashonaland are not nearly so promising today as they were a few months ago, that business is not nearly so brisk, and that Rhodesian mining properties and shares are in nothing like the demand they were. But to suppose that gold mining is a thing of the past is to adopt an erroneous opinion of the industry. The mineral output of the country is being well maintained; indeed, were a little more native labor forthcoming, an immediate and substantial increase of the gold output would result. More important still, a large amount of development work is being done. In fact, despite the shortage of native labor, the good work of exploration begun in 1909 has not been allowed to abate, but is steadily being continued. It is common knowledge that Rhodesia's great need has been development. The smaller mines, and indeed the majority of the larger projects of the country, possessed no ore reserves of any consequence whatsoever until a year or two ago when mining in Charterland was commenced on really sound and business-like lines.

In 1910 one of the leading mining men of Matabeleland remarked to me, that the next three years would show what place southern Rhodesia was to take in the list of the world's mineral producing countries. That view was a correct one. The exploratory work, now being conducted on the various mineral belts of southern Rhodesia, is going to either make or mar the country. Because the gold output is not rising by leaps and bounds, and because the many foolishly optimistic statements made at the time of the boom are not materializing, it must not be imagined that the country's industry is on the wane. Considering the paucity of the labor supply and the large percentage of the supply which is being devoted to development, the present production of Rhodesia must be adjudged satisfactory.

The gold output of Rhodesia since the beginning of 1910 has been as follows:

	1910.	1911.
January	£227,511	£207,903
February	203,888	203,055
March	228,385	231,947
April	228,273	221,296
May	224,888	211,413
June	214,709	215,347
July	195,233	237,517
August	191,423	243,712
September	178,950	225,777
October	234,928	218,862
November	240,573
December	199,500
	£2,586,201	£2,216,829

The scarcity of native labor in Rhodesia seems to become more serious as the months go by, and the situation today is causing great anxiety. The native population of the territories ruled by the British South Africa Co. is large, but it is one thing to possess a large native population and quite another thing to have a large working native population. Rhodesia's position in regard to native labor is certainly not enviable. She cannot hope to secure any appreciable or useful complements from the Transvaal or other territories of the Union of South Africa, nor indeed from a great deal of Portuguese East Africa, because the labor recruiting agents of the Witwatersrand have a monopoly in these areas. Nyasaland and northeastern

Rhodesia have wellnigh closed their doors to the southern Rhodesian province, the province in which all the important mines are situated. In both these states the dread scourge of sleeping sickness has lately advanced and increased to an appalling degree, and furthermore, the Nyasaland planters are loth to allow any of their none too plentiful laborers to seek work outside their own frontiers.

The mines of Rhodesia must in fact look largely to Matabeleland and Mashonaland, together with northwestern Rhodesia or Barotseland, as suppliers of native labor, and none too much is at present forthcoming from these territories. In regard to Barotseland, it may be remarked that native labor recruiting agents employed by the Tanganyika Concessions, Ltd., are scouring the territory for labor and are further adding to the tribulations of the southern province. In these circumstances it is not surprising to learn that the controllers of the Rhodesian mining industry are considering the employment of natives from parts of Africa other than those adjacent to Rhodesia.

It is understood that important proposals, which concern themselves with the West Coast of Africa, are now receiving the attention of the Executive of the Rhodesian Chamber of Mines. It is suggested that native labor shall be imported from Liberia, from Angola, and other places on the West Coast. Of course the concluding of satisfactory negotiations with the governments of these states has first to be arranged, and, as yet, no announcement has been made by the Rhodesian authorities in regard to these proposed plans. It is, however, quite clear that something must be done to relieve the stress of the situation, and if labor is not obtainable from the territories controlled by the British South Africa Co., the leaders of the industry in Charterland will have to look farther afield.

It is interesting to learn that at last the board of directors of the Tanganyika Concessions, Ltd., has decided to use the Wankie Colliery Co.'s coke. Hitherto imported coke has been employed for the blast-furnaces of the Katanga, and the cost of importation has placed a severe tax on the company's expenditure. The Wankie colliery is situated in northern Matabeleland, and it has for long been a matter for surprise, that no seeming attempt has been made to come to an arrangement with the only producing coal mine in Rhodesia. It as yet remains to be proved that the Wankie company is capable of producing a class of coke suitable for the Tanganyika Concessions company's needs, but it is at any rate of much interest to learn of this development in connection with the company's smelting program.

TORONTO, CANADA

COLD WEATHER PROMOTES WEST SHINING TREE PROSPECTING.—GENERAL FIELD NOTES.—DIVIDEND RECORD FAILS TO RELIEVE MARKET.

The extremely cold weather has seriously interfered with the construction work and surface operations at Porcupine, further delaying the completion of the mills at the Dome and other properties. The freezing of the lakes and streams has facilitated travel, and since the cold set in there has been a considerable movement of prospectors into the West Shining Tree district, where additional good finds are reported. The Timmins township, on Miller lake, which has now a population of about 600, has been incorporated as a town, being the first settlement in the Porcupine area to obtain the civic status. Within its limits are included the Hollinger mine, the Campbell Veteran claim, the Dixon and Miller-Middleton properties, and other holdings of the Timmins-McMartin-Dunlap syndicate. The force employed on the Bewick-Moreing properties has been reduced, operations during the winter being confined to the shaft at No. 1 camp and the camp near the Foley-O'Brien line. Ernest Williams, who has been in charge, is returning to London. At the annual meeting of the Dome on January 3, some important changes were made in the directorate. Ambrose Monel was elected president, with W. C. Edwards as first vice-president, and Messrs. De Lamar and E. C. Converse, both of New York, became members of the board. W. W. Mein, formerly of the Robinson Deep mine, South

Africa, was appointed consulting engineer. Henry Hanson, at present superintending the construction of the mill for the Merrill Metallurgical Co. of San Francisco, will join the Dome staff as mill superintendent when the mill is finished. The total expenditure on the Dome to date is stated to be \$800,000, exclusive of the loss in the fire last summer, which cost the company \$309,236 in excess of the insurance. The Hollinger has ordered 27 electric motors for its mill, varying in size from 10 to 100 hp., from the Canadian General Electric Co., to be delivered before the end of February. At the McIntyre a 28-ft. vein of mineralized schist and quartz, which it is hoped will yield good milling ore, has been opened up by a cross-cut from No. 1 shaft on the 200-ft. level. In cross-cutting on the 100-ft. level at the Imperial property, several small veins, all carrying visible gold, have been found. Operations will be resumed shortly at the Success, where a reorganization of the company has been effected by the withdrawal of the English stockholders. The Preston East Dome declined to make the third payment due for the Preston property, amounting to about \$25,000, so that the claim reverts to its former owners, the Logan Silver Mines, Ltd. The former company retains the three East Dome claims, which will be actively developed. The Gold Peak company, re-

GOLDEN STAIRWAY TRENCH, LOOKING TOWARD
DOME EXTENSION.

cently organized, has taken over eight claims in Turnbull and four in Ogden township owned by C. H. Moore and Archibald Brown. The Pearl Lake has ordered new machinery comprising a hoist capable of working to a depth of 1000 ft., a double-drum 10 by 12 machine, and 100-hp. boiler. The shaft has reached a depth of 225 ft., and a station for storage has been cut at the 200-ft. level. The Vipond shaft is to be put down from the 200-ft. level for 100 ft. farther. At 200 ft. the vein has been driven on for 65 ft., the ore carrying about \$24 per ton. The completion of the mill by spring is contingent on the delivery of material and machinery on time. The Lucky Cross, at Swastika, has cut a 6-ft. lens of quartz on the 100-ft. level.

The dullness of the Cobalt market is unaffected by the dividend record for 1911, which considerably surpasses that for the previous year. Excluding the close corporations and privately owned properties, 12 dividend-paying mines returned to their shareholders last year a total of \$8,395,558, as compared with \$6,460,817 in 1910. The total payments of dividends since the beginning of operations to the end of 1911 amount to \$28,611,131, and it is estimated that if the returns from the other properties were included, the aggregate would be about \$10,000,000. The most important happening in connection with the Cobalt district lately is the shipment, since the year opened, of what is stated to be the richest carload of ore so far sent out. It comprised 31.3 tons from the 500-ft. level of the Temiskaming, and contained 200,728 oz. silver, valued at \$110,397. The record was previously held by the Crown Reserve for a car of 19.9 tons, averaging 8903 oz. per ton.

The Nipissing statement for December shows a production of 407,114 oz. silver, valued at \$225,156. The cash on hand as of January 6, was given as over \$1,500,000, from which the forthcoming dividend of \$450,000 must be deducted. The La Rose directorate has adopted a deep mining policy for the main property. The winze, which was put down 120 ft. from the 250-ft. level, will be sunk an additional 100 ft., and at this depth a station will be constructed and extensive cross-cutting and driving done. A statement of the financial position of the McKinley-Darragh, on December 28, shows a total of \$605,441, including cash in hand, ore at smelter and in transit, and ore ready for shipment. The Coniagas is opening up new territory on the 75-ft. level with good results. Only 25 of the company's 40 acres have so far been prospected. A winze put down from the 225-ft. level on the eastern end of the property, where the conglomerate is deepest, is now 40 ft. down in good ore all the way. The mill is treating 186 tons of ore per day averaging 36 oz., though mine ore still furnishes over half the production. The cost of production is only 8.8c. per ounce.

The Ontario Government has withdrawn the islands in Lake Temagami from prospecting and from sale or lease. There is no reason to believe that valuable minerals exist there, and it is desired to keep the islands as a resort for tourists and sportsmen.

SALT LAKE CITY, UTAH

LEAD SMELTERS RAKE FIELD FOR CONTRACTS.—SMELTING AND MINING INTERESTS INVESTIGATE FERTILIZER MANUFACTURE.—FISH SPRINGS MINE REPORT.—BINGHAM EARNINGS.

Time was when the lead miner of Utah and the adjacent states was made to feel that he was indeed fortunate to get a smelter which would accept his ores at any price which would permit him to mine his ore. Times have changed. It isn't the miner who actually has developed ore who is now doing the worrying, but the smelter manager, and some interesting developments are now being watched for by people who understand the situation thoroughly. Ever since the International S. & R. Co. decided, a year or more ago, to put in a lead stack at the Tooele plant, there has been some general scrambling for lead ore. Rumors of a community of interest between the International (controlled by interests allied with the Amalgamated Copper) and the Guggenheim corporation, the A. S. & R. Co., apparently never reach the men in the field, as the fight for business is becoming hotter and hotter. Both sides have been scouring the country for contracts, offering all kinds of inducements, and the International has gone as far away as the Coeur d'Alene after ore. The big producers are sitting back and having a fine time, while the small producers who once had to sit for hours in the anteroom waiting their turn, and generally their turn-down, are now being courted and flattered. One of the largest and earliest contracts obtained by the International was that for the output of the Daly-Judge at Park City. For months, while the new smelter was being erected, the International has been buying the ore and stacking it up at Tooele. When the new lead smelter is blown in shortly, it will have enough Daly-Judge ore to last it for some time. All the companies are fighting for the rest of the Park City output, and here F. A. Heinze has bobbed up with a strong card to play. Mr. Heinze has a long-time contract for the output of the Silver King Coalition, the largest silver-lead producer in the state. He secured it when he was preparing to build a smelter in Utah. When he was obliged to give up that project at least temporarily, he still had the ore contract. He is now doing business with the A. S. & R. Co. It is stated that if he should divert this business elsewhere, it would be a serious blow to the Murray plant of the American, on account of the scarcity of desirable lead ores.

Smelting, mining, and agricultural interests are turning their attention to the chances for building up a fertilizer industry centring in Salt Lake City. A recent bulletin

of the U. S. Geological Survey states that Salt Lake and Ogden form logical centres for such an industry, because of the recent potash and phosphate discoveries in the surrounding country, and because of the immense amount of sulphuric acid which can be made as a by-product from the smelters. At present the manufacture of sulphuric acid from the fumes has not been attempted on any large scale, because of the lack of a profitable market.

The annual report of the Utah mine at Fish Springs draws attention to the record of this remarkable little mine, which is in the desert of western Utah, 75 miles from the nearest railroad station, at Oasis. The wagon-haul costs \$12 per ton, and yet the mine has gone steadily on for twenty years without closing down or levying an assessment. It has produced \$1,198,000 in silver-lead ore and paid \$281,860 in dividends. The 1911 production was 1,459,150 lb., the ore averaging about \$86 per ton. As a result of the recent visit to Utah of James P. Graves, president, and Henry N. Sweet, a director, of the Bingham Mines Co., it is announced that a more aggressive development campaign will be entered upon. Mr. Graves states that the net earnings for the year were \$112,000, out of which is deducted \$32,000 bond interest.

JOPLIN, MISSOURI

DECREASING THE COST OF SHAFT SINKING.—QUALITY OF JOPLIN ZINC ORES IMPROVE.—BIG DRAINAGE PLAN FOR AMERICAN MINES.

Through the installation of a deep well pump in an 8-in. drill-hole, seven feet from the shaft he is sinking, J. M. Short, owner and operator of the Geronimo mine on the Connor land in the western part of Joplin, has reduced his cost of sinking \$7.50 per foot. Formerly the cost was as high as \$25 per foot, due to the heavy volume of water that had to be handled before progress could be made and because of the necessity of either removing the pump which was in the shaft or guarding it with heavy timbers at each blast. The latter course often resulted in serious damage to the pump. The cost of sinking is now \$17.50 per foot. The shaft was down to a depth of 70 ft. when pumping arrangements were changed. The shaft is to be sunk to a depth of 126 ft., if ore is found at the expected level as indicated by drill clippings, taken from a hole on the site of which the shaft was sunk. About 56 ft., therefore, remains to be sunk. At the saving per foot mentioned the total saving will be \$415. The cost of putting down the 8-in. drill-hole near the shaft was \$150, which, when deducted from \$415, leaves a net saving of \$265. Had the system been adopted earlier the saving would have been greater. But the mere item of expense is not the feature of greatest importance. The saving of time is the chief item. Prior to changing pumps the company was sinking barely 5 ft. per week; the same work is now accomplished in 16 hours. This is the first time this method of shaft drainage has been tried in the Joplin district. It would appear necessary that the shaft be sunk either through open ground, thus permitting free drainage of water to the drill-hole, or that two drill-holes be sunk, one squarely in the centre of the shaft and the other nearby for the pump. At the Geronimo mine, where the shaft went through almost impervious limestone, it was necessary to follow the latter method. At this mine, open ground is found beneath the limestone, and both drill-holes penetrate this stratum. Thus, when the water descends through the drill-hole in the bottom of the shaft, care being exercised to keep the opening free from dirt, it enters the open ground, traverses the intervening space to the other drill-hole, and is raised with the deep well pump.

An assay taken from a conglomerate mass of zincblende, accumulated from small samples taken from scores of mines throughout the Missouri-Kansas district, exclusive of the low-grade mines of the Miami, Oklahoma, camp, shows the average metallic zinc content for the year 1911 to have been 57.10%, or an increase over the assays of past years. This condition was due to the opening of numerous mines which turned out a choicer quality of ore than is customary

in this district. However, the percentage of iron was much higher than usual, running 2.40%. In 1910 the figures were 56.55% zinc and 2.10% iron; in 1909, 56.30% zinc and 2% iron. In 1904, the banner year in the matter of choice ores produced, the zinc content touched 57.97%, and iron only 1.84%. One of the biggest drainage projects undertaken in Joplin district properties has just been completed by the American Zinc, Lead & Smelting Co., operating the largest sheet ground mines in Missouri. A drainage drift, 1000 ft. in length, connecting shaft No. 7, at the extreme north part of the developed area of the American land, with the old workings to the south, has just been finished. Aside from the novelty of the new drainage idea, this is the longest single drift ever driven by any company of the district. Machinery for a powerful central pumping plant at shaft No. 7 has been installed. Eventually the company intends to erect a concentrating-plant at the north shaft.

At the United-Lehigh mine at Carl Junction development is being conducted in sheet ground from one shaft, and in soft ground from another. At the latter, drifts have been driven under a substantial cap-rock of limestone, which is, in reality, the bedrock of the old soft-ground workings. The company, with raises through the limestone into the rich pillars left in the old ground, pulls the dirt down into the lower levels, from which it is removed to the mill. Mules, as underground car haulers, have been replaced with a rope haulage-system at the Golden Glow mine on the Underwriters' land at Webb City. Dirt is now being hauled underground from a point 700 ft. distant from the shaft.

The Webb City Smelting & Manufacturing Co., manufacturers of pig lead, has been taken over by the American Metal Co. The Webb City corporation was capitalized at \$75,000. The sale was made at a loss of \$20,000, which the stockholders bore. Smelters of lead claim there was little or no profit in the industry in 1911, and the Webb City plant, being a new one, having started barely a year ago, was not in position to withstand the pressure. The average price of pig lead through 1911 was about \$4.375 per 100 lb., East St. Louis quotations. Ore ranged in price from \$27 to \$32 per 1000 lb. In handling the ore the cost is divided as follows: 50c. for buying expense, 50c. for hauling, and 50c. for freight to the smelters for each 1000 lb. Add to this \$1.50 freight on metal per 1000 lb. to East St. Louis from the local district, and the total expense is \$3. The smelters claim a margin of \$10 per ton is necessary if they are to make a profit. In 1911 the margin was often under \$6.

AUSTIN, TEXAS

SIGNIFICANCE OF ELECTRA OILFIELD TO TEXAS.—STATE RANKS SIXTH IN PRODUCTION.

In a brief review of the oil development of the state, William B. Phillips, director of the bureau of economic geology and technology of the University of Texas, says:

"With the coming in of the Electra oilfield, Wichita county, 150 miles northwest of Fort Worth, which has now a production of about 10,000 bbl. per day, the oil situation in Texas has entered upon a new phase. With the exception of the Navarro county oilfields near Corsicana and Powell, practically all of the Texas oil has been obtained from the formations represented in the coastal plain counties of Jefferson, Hardin, Liberty, Harris, and Matagorda, which are upper Cretaceous and Tertiary. These are the formations which have yielded by far the greater quantity of oil produced in Texas, and they continue to supply the bulk of the oil secured here. In the Electra field, however, there is a different set of conditions. While the Cretaceous is represented, there are two, and perhaps three, other formations which are to be considered, the Carboniferous and the Permian, with beds which may prove to be Permian-Carboniferous.

"It is of interest to state the total production of petroleum in Texas since the earliest reliable statistics were gathered. Since 1889, including 1910, the total production of petroleum in Texas has been 147,460,188 bbl., each of 42 gal.

Considering the total production of the different oil producing states, Texas ranked sixth in the following order, Pennsylvania and New York, Ohio, California, West Virginia, Oklahoma, and Texas.

"The production in the United States since 1859 is given as 2,378,907,864 bbl. Texas reached its high-water mark in 1905 with 28,136,189 bbl. Since that time there has been a marked reduction in output, and in 1910 Texas produced 8,899,266 bbl. During the last five years the production diminished by 19,236,963 bbl. of oil."

GLOBE, ARIZONA

WORK STARTED ON KINGDON SHAFT.—NOTES OF DISTRICT.

The preliminary of concreting the Kingdon shaft of the Old Dominion company has begun, under the direction of Paul Michaelson, contractor, and C. H. Weideman, construction engineer. The work is being done under contract. The shaft will be concreted from the collar to a depth of 1000 ft. The work will be done in sections, beginning at

ARIZONA.

the top. This will be the first concrete-lined shaft in the Southwest.

Charles S. Smith, president of the Old Dominion and of the new Arizona Commercial company, is visiting the mines, and states that work will not be begun by the Arizona Commercial until the bonds of the old company have been foreclosed and the new company takes possession of the property, or some time in June or July. It is proposed to confine the work to the old Copper Hill shaft near the United Globe ground of the Old Dominion and to make some arrangement with the Superior & Boston whereby the latter company will develop the ground tributary to the Eureka shaft. James Neary, superintendent of the Magna copper mine at Superior, thirty miles west of Globe, states that 300 ft. of driving has been done on the eighth level, opening up a vein of rich copper ore as much as 15 ft. wide, the shipments averaging 26% copper. The mine formerly was known as the Silver Queen and is now owned by the Gunn-Thompson company.

Ore is being hauled from the Duquesne group, fifteen miles west of Globe, and loaded on the car at Miami preparatory to shipping to the smelter at El Paso. The ore is reported to run well in gold, silver, and lead.

At the Superior & Boston mine on Copper hill, the cross-cut north, from the McGaw shaft, on the twelfth level, is

within a short distance of the vein and is purposely being advanced slowly so as not to cut the Great Eastern vein before the arrival of the 200 ft. of 12-in. pipe for the water column between the twelfth and tenth levels. The present flow is about 750,000 gal. per day, most of which comes from the upper levels. The Miami Copper Co. continues to produce at the rate of 2,500,000 lb. of refined copper per month with five of the six units of the concentrator in operation. The sixth unit should be running by February 1 or a few days later. It is proposed to resume churn-drilling in the near future, but this work has not yet been started, as reported in some Eastern papers.

The Inspiration Copper Co.'s dam across Pinal creek, 16 miles from the mine, will be the chief source of water-supply for the concentrator. It will be built of concrete rubble masonry, will be 75 ft. long, and average 25 ft. high. There will be a concrete forebay and a tunnel to connect with the pumping station. The method of concentration recommended by J. M. Callow is being tested by him in the experimental mill. It is designed to be an improvement on the roughing system as practised in many of the large mills of the country. It aims, by means of graded crushing, to produce a comparatively small amount of slime.

LONDON

EL ORO'S FUTURE POLICY.—SAN RAFAEL VEIN TO BE EXPLORED IN DEPTH.

The El Oro Mining & Railway Co. has published a report made by R. T. Bayliss giving his views as to the future policy to be adopted at the El Oro gold mine, Mexico. He has recently paid a visit to the mine in his capacity as chairman of the company, and has conferred with R. M. Raymond, the local director, and A. F. Main, the manager. Their unanimous opinions are given in his letter. Upon personal examination on the spot, Mr. Bayliss is confirmed in his opinion that the upper part of the San Rafael vein, that is, above the 486-ft. level, affords no further prospect of new discovery, so he advises the suspension of development work. There is a large amount of ore remaining in the stopes, and he recommends that this be extracted without delay so as to curtail the item of expenditure which would otherwise be involved in keeping the workings in good order. The labor released by the abandonment of development in the upper workings is to be utilized in exploring the lower parts of the San Rafael vein, especially in the southern portion between the 486-ft. and 1000-ft. levels. The developments on these levels in the northern part have been disappointing, but strong hopes are held out that better results will be obtained at the southern end. On the branch or west vein the recent developments have been excellent. This orebody was first found in the 1000 ft. level and has now been proved to be continuous from the 786-ft. to the 1300-ft. levels. The ore is high grade and streaky, and much rock has to be broken with it, but the average content of the whole is \$17 per ton. The exact structural relation between the two is not yet quite clear. There are indications that somewhere between the 1000-ft. and 1150-ft. levels the two veins are adjacent if they do not actually join, but below this the branch vein dips away to the west. On the San Patricio vein the ore appears to be distributed in much the same way as in the San Rafael. After providing rich ore on the first and second levels, the vein gradually became lower, until on the fourth level no continuous orebody has been found. The indications are that at a lower level in the southern part richer ore will once more be found, as happened on the San Rafael. Mr. Bayliss writes hopefully of No. 4 vein, still farther to the west, and recommends that development work should be continued. As regards the future policy of the company, Mr. Bayliss recommends that the extraction of ore from the San Rafael be reduced to 20,000 tons per month, expected to yield an annual profit of £150,000 per year, or £50,000 less than at present. In the meantime the developments at depth in the San Rafael, the San Patricio, and the No. 4 will, it is hoped and confidently expected, provide a continuation of the ore supply for the mill.

General Mining News

ALASKA

PRINCE WILLIAM SOUND

Three hundred and fifty tons of high-grade copper ore was shipped early in the month from the Fidalgo-Alaska mine to the Tacoma smelter. This is the first shipment made from the property.

THE TANANA

From a recent mill-run, it is estimated that the last 10½ tons of ore from the Rexall group will yield \$180 per ton. The Rexall group is on Wolf creek, and is operated by Cooper & Stillman, lessees.

Shaft-sinking will be started in the near future by August Peterson, layman on 17 Goldstream. H. H. McDonald, one of the owners of the claim, is in charge of the property.

ARIZONA

GILA COUNTY

Three drifts have been started from the station on the 800-ft. level in No. 2 shaft of the Live Oak mine and all are breasted in ore. Drifts and raises are being driven on ore at the east end of the orebody on the fourth level.

PINAL COUNTY

January's production of the Ray Consolidated, it is expected, will pass the 3,000,000-lb. mark, the increase being possible both by the higher grade of ore treated, and also by greater tonnage handled per unit of concentrator, which has been treating about 4000 tons of ore per day in the four units which are in commission. The fifth unit is now operating, while the second has been shut down for the purpose of making certain adjustments to conform to the No. 1, or model unit, it being the intention to shut down one unit at a time until the necessary adjustments have been made for the entire plant. The average grade of ore treated at Ray during November was 1.75 to 1.80% copper, as against the average of the company's ore reserves of 2.17%. On this grade of ore, extraction in the concentrator has been running nearly 70%. The cost of producing copper at Ray Consolidated at the present time is approximately 9c. per pound, based on smelting concentrate at Hayden. The sixth unit of the mill is to be ready about April 1.

YAVAPAI COUNTY

(Special Correspondence.)—Oil excitement still continues throughout the Verde river district, there being three rigs at work, and more reported on the way. William Stephens reports the drill of the Verde Valley Oil Co., near Camp Verde, to be down over 200 ft. and work progressing rapidly. The new Verde line of the Santa Fe is now working five different crews on grading work, and steel has been laid for several miles out of Cedar Glade.

S. S. Ballard and Thomas Martin, owners of the patented group of claims known as the United Verde Junior property, have bonded the same to A. H. Lyons and W. M. Malody for \$12,000 cash or \$25,000 in two years. Messrs. Lyons and Malody subsequently assigned the bond to the Black Hills Copper Co., which adjoins on the west.

It is reported that work will start, in the near future, on the 10,000-ft. adit of the Jerome Tunnel company. The portal of the adit will be almost due east from Jerome and will run directly under the town, tapping the United Verde mine at a depth of about 1600 ft., and several other valuable properties at nearly the same depth.

Prescott, January 20.

YUMA COUNTY

The D. & W. M. Co.'s annual report, recently issued, states that milling-grade ore has been opened up on five levels, to a depth of 700 ft. The underground development amounts to 3150 ft., and with a mill the property could easily be put on a paying basis, according to J. W. Fink, president and general manager for the company.

CALIFORNIA

ELDORADO COUNTY

It is reported that M. P. Powell and R. S. Young have sold the Humiston and Eureka quartz properties to San Francisco capitalists. The mines are in the Latrobe district.

KERN COUNTY

Late newspaper reports state that the Antelope Valley G. M. Co. is about to build a mill to treat ore by amalgamation. The company's property includes the vein discovered several years ago by E. M. Hamilton.

SAN FRANCISCO COUNTY

A. B. Ruggles, recently reelected president of the San Francisco Stock Exchange, has announced the following appointments: Governing committee, A. F. Coffin, William Bannan, George S. Clark, C. D. Laing, E. P. Barrett, T. S. Robinson, and J. Kullman; finance committee, E. Epstein, W. H. Hannon, and G. C. Sneider; membership committee, J. H. Berghauer, Edmond Godechaux, W. H. Moise, W. J. Hayes, and J. McKenzie; stock list committee, F. D. Atherton, R. L. Colburn, S. D. Landecker, Fred Rodda, and B. L. Wilson. In the first committee T. S. Robinson replaces B. F. Shaw, who declined to serve, and J. Kullman replaces Nat Boas, who is about to leave the city for some time, while otherwise the committee is as last year.

SHASTA COUNTY

(Special Correspondence.)—The Mammoth Copper Co. has started preliminary work for the installation of another bank of cooling pipes, making nine in all. This will enable the company to operate three furnaces throughout the year. Current rumors are to the effect that an attempt will be made to operate the Balaklala smelter during the present year, by treating the fumes with the Cottrell system and a sulphuric acid annex. It is understood an active development campaign is about to be started at the Golinsky copper mines by the German syndicate, which acquired the holdings last fall. Albert Vestal has acquired eight claims of the White Oak group, in the Lower Springs district. George F. Graves, of Redding, and Frank Bein, of Kennett, were the former owners.

Redding, January 20.

The Quartz Hill mine, Old Diggings, and the Mt. Shasta mine, Shasta district, have been shut down. It is said they will resume in the spring.

TUOLUMNE COUNTY

(Special Correspondence.)—The Bonanza pocket mine, first worked in 1851, and which has yielded about \$2,000,000, is being unwatered and retimbered for another period of activity. It is situated in the northern part of Sonora, completely surrounded by residences, and has not been worked for nearly twenty years, though there is yet considerable ground that has not been explored. The vein is in a slate formation and is from 4 in. to 1 ft. wide. The property was lately bonded to Los Angeles men, among whom are R. L. Summerland, A. J. Koll, and C. W. Mitchell.

John Witney has become interested in the Humbug Tunnel mine and intends to explore the property. A deposit of gold-bearing gravel was uncovered a short time ago. The outlook at the Omega is reported to be good. The working crew has recently been considerably increased, and in a short time the mill will be started. At the Saratoga gravel mine, on Table mountain, operated by V. J. F. Dien and associates, the gravel deposit has been reached. Arrangements are being made for electric power at the Columbus mine, near Tuolumne. The construction of an electric transmission line to the Slap Jack has been completed and the property is now being unwatered. Actual mining will begin about February 1.

The crew of men which was engaged in reopening the Mayflower mine, bonded only recently by W. H. Scott to W. P. Daniels, has been withdrawn owing to some disagreement between the parties to the bond. Outcroppings of a large vein on a 5-acre tract in the southern part of Tuolumne recently purchased by Frank Paff for a residence

assay up to \$20 per ton. The vein will be opened by sinking a shaft.

Tuolumne, January 20.

YUBA COUNTY

While other officers of the company decline to discuss the action, it became known recently that E. W. Tarr has resigned as general manager of the Tarr M. Co. His resignation will be acted on at a meeting near the end of this month. He organized the company and was one of the leading members throughout the five years of its existence.

COLORADO

DENVER COUNTY

At a meeting at Denver, January 13, of mining men of the state, an organization was formed with the avowed purpose of exterminating wild-cat mining companies and of preventing fraudulent misrepresentation on the part of miners and prospectors. R. Kenelhan, State Treasurer, was elected president. No name as yet has been selected for the body.

EL PASO COUNTY

The ninth Edwards roaster is to be installed at the Golden Cycle mill at Colorado City February 10, according to Hugh McGarry, general manager for the company. A kominuter, for fine-grinding and preparing the ore for

ISABELLA MINE, BULL HILL, CRIPPLE CREEK.

the roasters, has been put in. Both the Cycle and the Portland mills are reported to be operating at capacity at the present time. In an official statement Mr. McGarry has denied any reported sale of the Golden Cycle M. Co. property to the A. S. & R. Company.

LAKE COUNTY

At the big Chief an incline shaft will develop a large zinc-carbonate orebody. The incline will be sunk from the bottom of the present shaft, 800 ft. deep, where a 22-hp. electric hoist will be placed. About 700 ft. of wire will be required to supply power from the surface. About 25 cars of ore per day is being shipped from the Castle View, and a similar amount from the Creseent and Catalpa. Other properties of the district are being actively developed. Among them, work has been resumed in the South Winnie shaft on Breece hill.

PARK COUNTY

The Mill Gulch M. Co., operating about 25 miles north of Cripple Creek, claims to have discovered a large deposit of copper ore assaying 2.4 to 23.3% copper. R. K. Thomas, of Colorado Springs, who is at the head of the Colorado Development Co., asserted that an offer of \$200,000 for the property has been refused. It is rumored that the A. S. & R. Co. made the offer.

TELLER COUNTY (CRIPPLE CREEK)

The Mary McKinney M. Co., the oldest corporation in Cripple Creek, will legally expire March 31, and steps are being taken toward reincorporation.

Linderfelt & Stewart have secured a lease on the Deadwood mine, Bull hill. Eight sets of sub-lessees are developing the property at present.

The Modoe M. Co.'s board of directors and officers were

reelected at the annual meeting of the company, January 17. Two dividends, each requiring the disbursement of \$5000, were paid during the year. Work is to be started soon on the 1100-ft. level, 200 ft. below the present depth of operation. The tonnage shipped during 1911, according to the annual report, averaged \$44.50 per ton. All of the company's ore is shipped to the Eilers smelter at Pueblo. The total production was about 1700 tons. Two sets of lessees are developing the property, and it is stated that the policy of keeping the development ahead of the actual production will be maintained.

A quartz vein assaying \$42 to \$600 per ton, on the Smuggler claim of the Isabella group, Bull hill, has been found. The discovery was made under Lesler Grant, superintendent for the company, and not by lessees.

Gillingham & Burns, lessees, have discovered ore assaying \$30 to \$200 per ton on the fifty level, Morning Glory No. 4, of the Work Gold M. & M. Co. property.

MONTANA

LINCOLN COUNTY

(Special Correspondence.)—It is believed that there is considerable gold in the ground upon which Libby is built, this having been demonstrated recently by panning the gravel from a hole that has been excavated for a bridge pier. There are alternate strata of gravel and clay in the wash under the town, and in the gravel the gold seems to be quite plentiful.

A. M. Balfour is in town from the Blacktail mine, in the West Fisher gold belt. Work has been suspended at the property for the winter, but will be resumed as early in the spring as the weather will permit. Mr. Balfour and his associates have a lease on the property, which is equipped with a stamp-mill.

Libby, January 22.

SILVERBOW COUNTY

(Special Correspondence.)—It seems quite probable that W. A. Clark will introduce into this district a German process for treating zinc ore which, so far as experiments with zinc ore from Clark's Elm Orlu mine are concerned, have proved highly successful. A Butte man who has inspected the German process while abroad, says that the Butte zinc ore contains from 1 to 3% iron, 2 to 4% manganese carbonate, 1 to 2% chalcopryrite, 15 to 22% sulphur, insoluble complex silicates and quartz constituting the gangue matter running as high as 56%. After some experiments, the German who conducted them said that he did not see technical difficulties in treating the Butte ores, as similar ores had been treated successfully. With Butte ores containing a large percentage of complex silicates, a rough concentration will be necessary to remove a large part of the gangue. That can be accomplished without causing noticeable losses in the metallic content of the ore and ought to concentrate more than 90% of the metallic compounds from ore containing 18 to 20% zinc. The Butte product would assay about 30% zinc, and it would be an excellent material for the German process, the lime in the gangue remaining in the concentrates, with additional lime, crushed coal or coke breeze necessary for making bricks, with the concentrate or crushed ore, would be sufficient as flux. The ore is also roasted to overcome the greater percentage of sulphur. Some further tests are to be made in the presence of a representative of Mr. Clark, and if they are successful the process will be introduced in this district.

Butte, January 20.

NEVADA

CHURCHILL COUNTY

The Nevada-Fairview M. Co. has levied an assessment of 1½¢ per share to provide for a "small indebtedness created on account of the necessity of doing assessment work on the unpatented claims, and also to provide for the patenting of these claims during the present year, thereby obviating the necessity of expending any further money for assessment work."

CLARK COUNTY

The Quartette shaft has intersected the orebody at the

1350-ft., its lowest, level. A 15-hp. hoist has been erected at the Princess shaft of the Searchlight-Spokane property, where driving is about to be started from the 370-ft. level. The mill is being prepared for operation. Some changes are to be made in the mill at the Lucy Grey property, Crescent district, of which Carl Anderson is manager, says a report from Searchlight.

ELKO COUNTY

The Bourne mill is running steadily and treating about 45 tons of ore per day. The grade of ore is improving and the shipments of bullion have increased. The Pavlak mill is treating a good grade of ore. In the mine connections are being made to improve the ventilation which will be completed in a few days.

At the Bluster-Success properties, which are under option to George Wingfield, about 30 miners are employed. Four adits on the Success have been driven on the vein, all showing good milling ore with a fair amount of high grade. At the Bluster the cross-cut adit will soon tap the vein at a depth of about 300 ft. The Buckeye company has bought off the contractor who had charge of the development work on that property, and it is expected the Syracuse, New York, people who have an option on the property at \$250,000 for 75% of the stock will now take hold. The vein is showing a large quantity of milling ore with streaks of high grade. The Alpha and Flaxie are under option. Development work is being done on both properties.

LINCOLN COUNTY

A contract for the construction of the Prince Consolidated railroad, about nine miles long, has been let and the work will be started in the near future; it is to be completed by April 15. The line will obviate an expensive wagon-haul in delivery to the Tooele smelter. T. J. Bivens will be the engineer in charge of the road. The contract was let to the Thompson company, of which George Thompson, of Salt Lake City, is manager.

LYON COUNTY

The new Mason Valley smelter recently made its first shipment of matte, amounting to 9 tons, to the A. S. & R. refinery at Garfield. The matte was 40 to 60% copper, which at Garfield will be refined to commercial copper ingots.

The Copper Belt railroad is said to be doing well. Another locomotive, making three in all, has been put in operation. An average of 1600 passengers per month, principally those to and from Reno, and a heavy freight business have been developed. The passengers are handled with a gasoline motor car which makes regular trips.

W. Mont Ferry, president of the Yerington Central Copper Co. has written another note to stockholders urging them to sign proxies in order that a unanimous vote may be taken to make the stock assessable. The letter repeats that the directors believe that ultimately the property may be sold for more than the debts of the company, so that stockholders may receive a return for their money.

The Peer Gold Mining Co. has been incorporated to develop the Peer, Bernice, and Annex claims on Mt. Como, near Dayton. H. C. Cutler, of Reno, is president of the company, which is capitalized at \$1,000,000 in \$1 shares. The claims adjoin the Nevada Deep Mines property.

It is rumored that a group of Eastern capitalists will take up the remaining \$50,000 in bonds on the Nevada-Rockland mine, 26 miles southwest of Yerington, and operate the property. It is said that they will rebuild the mill. Among them are G. A. Dittlinger and R. J. Palmer of Pittsburgh, R. F. Stevenson of Washington, Pennsylvania, and A. Vignos of Canton, Ohio. These men inspected the property January 23.

NYE COUNTY

It is rumored that a body of unusually rich ore has been found on the 400-ft. level of the Poak-Steen-Cicala lease.

The report of the Tonopah Midway M. Co. for the year ended December 31 shows a balance on hand in the banks of \$35,521, receipts from ore of \$47,528, and from the sale of a fraction, \$5000, making a total of \$88,049. Disbursements were: labor, \$34,606; superintendence and salaries,

\$5100; geology, \$385; supplies, \$6384; water, \$1268; lumber, \$1154; fuel, \$7974; assaying, \$1072; general, \$3039; legal, \$88; insurance and taxes, \$746; balance with banks, \$7849; due from Nye & Ormsby (suit pending), \$16,799; total, \$88,049. Shipments of ore amounted to 2035 tons, valued at \$65,700. Transportation and treatment cost \$18,173, leaving a net value of \$22.35 per ton. A total of 2665 ft. of development work was done, against 32,771 ft. the preceding year.

For the quarter ended November 30, 1911, the Tonopah Belmont Development Co. made the following report: Receipts from sales of ore bullion, \$884,161; expenses, \$427,114, leaving net earnings for the quarter of \$457,046; miscellaneous income brought the total net income up to \$463,672. There was due from smelters, loans on collateral and cash in banks, November 30, 1911, \$1,292,072. The total income of \$463,671 for the quarter ended November 30, compares with \$454,377 for the quarter ended August 31. Based on the last quarter, Tonopah Belmont is making net earnings of approximately \$1,850,000 per annum. The company has 1,500,000 shares outstanding, on which \$1 per share per annum is being paid. The present rate of earnings indicate that Belmont is adding approximately \$350,000 to its present large surplus.

During the quarter ended November 30 the Tonopah Mining Co. made the following monthly profits: September, \$132,349; October, \$153,536; and November, \$172,316; making a total of \$438,201. These figures somewhat exceed those of the preceding quarter, when net earnings amounted to \$418,025, which, with miscellaneous income, made a net of \$432,885. Tonopah Mining Co. is paying \$1.60 per share per annum on its 1,000,000 shares of stock. At the present rate of production, the company is maintaining a surplus above dividend requirements of from \$125,000 to \$200,000 per annum.

An 18-ft. quartz vein assaying about 78 oz. silver and 1.2 oz. gold has been discovered on the 1000-ft. level of the Mizpah Extension mine, according to a recent report from Tonopah. The Tonopah Belmont Development Co. main shaft is reported to have intersected the Belmont vein at a depth of 1375 ft. The McNamara M. Co. mill has been put in operation, making four plants at Tonopah. These, with the two at Millers, give a total of 260 stamps dropping in the district.

The shipments from the Tonopah district last week were as follows: Tonopah M. Co., 3500 tons; Belmont company, 2550 tons; Tonopah Extension, 948 tons; West End, 700 tons of ore. The total production, 8513 tons, was valued at \$212,825.

STOREY COUNTY

At the regular meeting of the Alpha Con. M. Co., January 18, the old directors were reelected. An assessment of 5c. per share was levied on the capital stock.

WASHOE COUNTY

New engines will be erected at the Reno-Ruhl G. M. Co.'s property and a double shift employed in the near future. Five buildings have been completed recently. The property is three miles north of Reno. At the annual meeting, held in that city January 22, C. S. Laumeister, Sr., of San Francisco, was elected president of the company, for which W. J. Thompson is superintendent.

WHITE PINE COUNTY

The Eastern M. Co., backed by New York investors, has taken an option on five gold claims from A. R. Nuekolls and Fred Borchert, of Cherry Creek, for a reported price of \$25,000. It is stated that \$6500 cash has been paid. W. A. Douglas is president of the purchasing company, and E. E. Everhardt, of New York, secretary-treasurer. The company was represented in the deal by Mr. Douglas. A 1000-ft. adit will be the first development undertaken, and it is rumored that a mill may be built. The property is in the Cocomongo district.

NEW MEXICO

GRANT COUNTY

(Special Correspondence.)—Two units of the Hurley

concentrator at the Chino Copper Co.'s plant have been put in operation, and a third will be placed in commission about March 1. Construction work for two additional units to the mill is well under way.

Hurley, January 16.

UTAH

JUAB COUNTY

The Gold Chain last week shipped 12 cars of ore. Lessees in the Gemini are reported to be developing new ore. It is rumored that the Grand Central shaft, now 2200 ft. deep, will be sunk farther. The Montana shaft has been sunk to a depth of 265 ft. Other properties in the district are active, and it is rumored that an assessment will be levied to provide for resuming development at the Tintie Central mine.

SALT LAKE COUNTY

The South Hecla M. Co. has levied assessment No. 1, of 6c. per share, delinquent February 20. The report for the period September 15, 1900, to December 31, 1911, states that 416 ft. of drifts and 62 ft. of raises have been driven, and some timbering has been done in the Quiney and Dwyer adits. Two small shipments of ore were made to

UTAH-APEX MINE.

test the property. More shipments were prevented, it is stated, in February by a contract to transfer the property in exchange for 120,000 shares capital stock of a new corporation designed to acquire also the properties of the City Rocks M. Co. of Utah and the Grizzly M. Co. of Wyoming. The deal ultimately fell through. The cash statement shows receipts of \$22,365, of which \$10,000 was from a note, \$10,503 from sale of stock, \$1170 from the boarding house, and \$692 from sale of ore. The company has on hand \$110. The resources of the company are rated at \$515,954, including the treasury stock, and the liabilities at \$512,604.

The Kirk & Leavell engineering firm has secured a lease on the workings of the Utah-Apex mine from the 400-ft. level to the surface. The same lessees are operating the Last Chance and Horace Greeley group.

Despite urgent orders, additional equipment for the Bingham & Garfield railroad has not been delivered. The Utah Copper Co. is handling all of the ore possible with the present rolling stock. Six sections of the Arthur mill have been remodeled.

TOOELE COUNTY

E. P. Mathewson is quoted as saying that owing to high freight rates the lead refinery planned by the International S. & R. Co. will not be situated at Tooele, Utah, where the company's lead smelter is to be blown in some time in February. The blast-furnaces have been completed, and about a third of the bags have been hung in the bag-house.

WASHINGTON

FERRY COUNTY

(Special Correspondence.) The Knob Hill Co. has furnished the following report of its operation and produc-

tion from August 1, 1910, to January 1, 1912: 577 tons of ore shipped to the smelters had a gross value of \$29,094.73; freight and treatment charges \$5364.90; net value \$26,630. During the year 1911, 6565 tons of ore was shipped, having a net value of \$135,275; total ore shipments, 7142 tons; gross value, \$224,795; freight and treatment charges, \$75,789.67; net value, \$149,005.09. The average net value per ton was \$20.89; metals produced, 10,850 oz. gold and 31,914 oz. silver. During 1911 the work in the mine amounted to 2622 ft. Two stations on the fourth level were cut.

The North Washington Power & Reduction Co. is finishing its mill with waterproof siding. The boilers are being slow-fed, to dry out, preparatory to putting on steam. The steam and compressed-air lines are being distributed, and on arrival of some missing pipe, the generator will be put in motion, to relieve the company's main electric lighting plant of an overload. This arrangement will be temporary, while the company is building a transmission-line from the British Columbian boundary, it having a contract for the sale and distribution of light and power for Ferry county and surrounding mining districts south of the boundary line, from the West Kootenai Power & Light Co., at Bonnington falls, B. C.

The Republic Mines Corporation has opened on the 400-ft. level of the Surprise mine, a stope 70 ft. long, having an average width of 5 ft. on ore averaging about \$20 per ton. The main incline shaft on the Surprise is down 540 feet.

The San Poil Consolidated company is laying in concrete retaining walls for its mill. The Hope company is still continuing its operations to the winze going down from the adit-level, which is nearly completed.

Republic, January 19.

WYOMING

FREMONT COUNTY

Quartz mining is reported to be drawing many to Atlantic City, about 35 miles south of Lander. There are placer properties there, too, it is said, which would prove valuable if sufficient water could be secured. One company claims to be producing about \$8000 worth of gold per month.

CANADA

BRITISH COLUMBIA

The Portland Canal M. Co.'s report for the year ended October 31 has been published, and includes the following items. Expenses, \$83,332; receipts from ore, exclusive of concentrate and on dump, \$18,433; liabilities, 10% debentures \$87,500, sundry creditors \$24,485, loan \$15,000; cash on hand, \$2927. The property is valued at \$538,277, the plant at \$129,840, mine development at \$56,599, and other assets at \$9320.

ONTARIO

The Crown Reserve M. Co., Ltd., has declared its January dividend, No. 24, of 2% and a bonus of 3% for the same period, payable February 15 to stockholders of record January 31. The transfer books will not be closed.

Shipments from the Cobalt district during the week ended January 12 amounted to 118,750 oz. bullion, valued at \$64,602, and 246 tons of ore. So far this year the district has shipped 467 tons of ore and 190,647 oz. bullion valued at \$103,907.

Stockholders of the Green-Meehan M. Co., Ltd., at their annual meeting, authorized the property to be sold for \$150,000. E. W. Wright was elected president of the company.

YUKON

A report from Dawson states that John McCrimmon found a nugget weighing over 84 oz. on Barker creek, near Stewart City.

MEXICO

CHIHUAHUA

Machinery is being purchased for the new 40-ton mill of the Leon Grande G. M. Co. at Santa Rosalia. The company, after a year's development work, is about to start actual production, according to recent report. Matt Hoveek

Among the Copper Mines

At the Inspiration the experimental mill is running steadily and the temporary warehouse is finished. Underground work has not yet been resumed.

The Tuolumne new surface plant, Butte district, will not be in commission before the middle or latter part of the month, as some delays have occurred which were not anticipated.

Drilling in the Butte mines by electricity has been proved practicable through the experiments carried on by the North Butte company, and the equipment of all drilling machines in the company's mine for operation by electricity is now in progress. While the officials are non-committal at present, it seems to be understood that the Anaconda company will introduce the same system in the near future.

The new Butte & Superior company concentrator, on which work has just been started, will have a capacity of 750 tons per day instead of 500 tons as was originally intended. The company is now maintaining shipments of 500 tons per day, and with the ore blocked out shipments of double that amount could easily be kept up for a long period of time, so it has been decided to make the mill capacity 750 tons. Some of the directors were in favor of making the capacity 1000 tons per day, but A. B. Wolvin, president of the company, opposed this, taking the view that if it should be found that the mill should have the greater capacity it could be increased later.

Ore reserves at the leading porphyry mines, with the number of shares that will be outstanding when all bonds are converted and the proposed annual capacity of the mills, are estimated by George L. Walker as below:

Company.	Tons ore demonstrated.	Shares when all issued.	Treatment tons ore annually.
Utah Copper.....	320,000,000	1,619,349	8,500,000
Nevada Consolidated....	40,000,000	1,998,892	3,000,000
Miami	18,000,000	749,000	1,000,000
Chino	54,000,000	800,000	1,750,000
Ray Consolidated.....	75,000,000	1,350,000	2,800,000
Inspiration Consolidated.	45,300,000	927,500	2,625,000

Developments at the Lake Copper property continue satisfactory, and within a few months regular production should commence, says the *Boston News Bureau*. The shaft is now bottomed at the ninth level, where a station has been cut, but little or no driving has been done here as yet. One side of the new skip-road is expected to be in readiness within a few days, but the other side will probably not be done until the middle or latter part of February. By March, however, all construction in the shaft should be finished, and then all that will remain to be done is to make a clean-up underground preparatory to stopping and hoisting regularly. This may take a month or two, but production certainly should not be delayed much beyond the early part of May.

It is expected that early in February operations will be resumed in the Robert Emmet company mine, Butte district, of which W. Q. Ranft, of New York and Boston, is president. An unusually heavy flow of water and a lack of the money necessary to carry on operations necessitated a suspension of work some time ago. Mr. Ranft, in calling a meeting of the stockholders for January 22, announced that all financial arrangements had been completed to discharge pending obligations and that sufficient money is left over to meet operating expenses for some time to come. The shaft of the Robert Emmet is down to a depth of 500 ft., and it is intended to carry it down at least 200 ft. more, and for that purpose a lot of new machinery has been ordered. At the time it was necessary to cease operations a fine body of ore had been found.

Obituary

J. B. HOBSON, who died at Victoria, B. C., this month, was one of California's pioneer mining engineers. Born in Ireland in 1844, he came to California as a boy and began work in the mines. He was prominently connected with hydraulic mining in Placer county and was instrumental in organizing the California Miners Association. He was one of the men who secured the passage of the Caminetti bill, but when that failed to rehabilitate hydraulic mining he went to British Columbia, where he opened the Cariboo and Horsefly hydraulic mines in the Cariboo district for Sir William Van Horn and his associates. When the properties were sold to the Guggenheims he remained as the manager. Recently he has been active in development of other properties in the Province. Mr. Hobson served a short term as assistant to William Ireland when the latter was State Mineralogist of California and he was active in many ways in the development of Western metal mines.

JOHN WALTER YOUNG, second vice-president of Chalmers & Williams, Inc., died January 14 at his home, Evanston, Ill. Mr. Young, who was 56 years old, had heart disease for several years. He was born in Brooklyn, New York, in 1855. He was graduated from the Brooklyn Polytechnic Institute and went to Leadville in 1878. From then on he was actively concerned with metallurgical development in America, having been associated at various times with Karl Eilers, W. B. Frue, Walter McDermott, and other leaders. He turned his attention to the manufacture and sale of mining machinery and did much to build up foreign trade in that line of goods. In 1890 he became vice-president of Fraser & Chalmers, and from 1900 to 1907 was European manager for the Allis-Chalmers Co. Mr. Young was a member of the American Institute of Mining Engineers, the Montana Society of Engineers, the Chicago Club, the Midwood of Brooklyn, Engineers of New York, and the Alta of Salt Lake City, Utah. He was well and favorably known throughout the wide circle of American mining men.

ARCHIBALD G. BROWNLEE, who died at Idaho Springs, Colorado, January 16, was one of the group of brilliant Canadians who have done so much to develop the mining and metallurgical industries of the United States. Born in Ottawa in 1857, he came to this country when seventeen years of age. He served in the United States Army and later in the Indian service. Finally he went into mining, to which he devoted the greater part of his life. At the time of his death he was manager and principal owner of the Stanley mine at Idaho Springs, and was also interested in the Japan-Flora and other properties. He was a capable manager and won success. He found time for wide reading, for pictures and travel, and for public service. He was one of the directors and a member of the executive committee of the American Mining Congress, and was active in the building of a mill at Georgetown to test the Malm process on a commercial scale. He was a modest, likeable man who did good work and will be sadly missed.

ERNEST R. BUCKLEY, who died at the Stratford Hotel, Chicago, January 19, from pneumonia, was one of the younger generation of geologists, devoted to economic work. He was born in Massachusetts Sept. 3, 1872, and graduated from the University of Wisconsin with the degree of Ph.D. in 1898. He served successively as Assistant State Geologist of Wisconsin, Director of the Missouri Bureau of Geology and Mines, and mining geologist for the Federal Lead Co. Lately he had devoted his whole time to consulting work, having but recently opened an office in Chicago. Mr. Buckley's death was entirely unexpected, he having but just returned from a professional trip to the West. He possessed a vigorous intellectual honesty which required him to carefully re-examine the premises upon which any work was built, and was a painstaking student of ore deposits whose writings constitute an important contribution to the science of ore genesis. One of the last of his papers

on the subject formed a chapter of 'Types of Ore Deposits' and dealt with the Missouri lead region that he knew so well. Mr. Buckley, however, found time for duties other than technical. He served at various times as Sunday-school superintendent, city alderman, and as director, vice-president, and later president of the American Mining Congress. To the latter he devoted much time and labor, and it is but fair to say that much of the success that has come to the Congress was due to his work. Mr. Buckley leaves a widow, but no children.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

S. H. BALL is in Arizona.
A. P. ROGERS is in Arizona.
GEORGE H. GARREY is in Mexico.
C. W. MERRILL has gone to Colorado.
KARL EILERS was at Denver last week.
J. NELSON NEVIUS is in San Francisco.
J. B. LIPPINCOTT was in San Francisco.
S. W. MUDD has returned to Los Angeles.
C. T. DURELL was at Kalgoorlie last month.
G. W. METCALFE was in San Francisco recently.
J. W. MALCOLMSON is expected in San Francisco.
JAMES O. CLIFFORD is at Santa Rita, New Mexico.
COURTENAY DEKALB was in San Francisco last week.
T. A. RICKARD is expected in San Francisco in March.
F. B. WEEKS is at Paradise, Butte county, California.
JOSEPH BARRELL is lecturing at the University of Illinois.
MORTON WEBBER has returned to New York from London.
W. W. MEIN has returned from New York and Porcupine.
E. A. PRENTIS, Jr., is at the Ventanas mine, in Durango, Mexico.
W. H. EMMONS will lecture at the University of Chicago April 1 to June 20.
K. ITO and T. WATANABE, of the Nippon Oil Co., are visiting California oilfields.
F. C. GILBERT has gone to Panama, but will return to Colorado early in February.
RICHARD KLEESATTEL will be in Arizona and Mexico till spring, on examination work.
A. C. VEATCH is at Los Angeles and will be in the California oilfields for some weeks.
GEORGE E. WEBBER is in San Francisco, which he will hereafter make his headquarters.
E. V. DAVELER is assistant superintendent for the Ray Con. Copper Co. at Hayden, Arizona.
WILLIAM KNOX has returned to San Francisco from London and will leave for Nikolaievsk.
THEO. H. M. CRAMPTON has been examining the property of the North Fork M. Co., in Colorado.
S. T. WELLMAN has completed his work on the electric furnace at Heroult, California, and returned to Cleveland.
ARTHUR D. LITTLE has been nominated as a member of the corporation of the Massachusetts Institute of Technology.
C. M. EYE is returning from the Philippines by way of Europe. For the present his address is 1012 Sawatch street, Colorado Springs, Colorado.
H. B. BARLING has been appointed manager in Honduras for the New York & Honduras Rosario M. Co. Mr. Barling's address until further notice will be in care of the above company at San Juancito, Honduras, Central America.
THE regular meeting of the San Francisco Section of the Mining and Metallurgical Society will be held following dinner at the Palace Hotel, Monday, February 5, at 6:30 p.m.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

MARKING BOUNDARIES OF MINING CLAIM—CONFLICTING LOCATIONS

Where stakes were set to mark the boundaries of a mining claim and the proper notice posted, this is a sufficient marking upon the ground, although the corner stakes were not inscribed with the name of the claim. And the fact that a mining claim which has gone to final entry without adverse claim includes the original discovery on which a prior claim was based, does not necessarily defeat the right of the prior locator to the remainder of his claim, if other veins have been discovered on such portion and it is shown that there was no actual intent to abandon the claim.

Bingham Amalgamated Copper Co. v. Ute Copper Co., 181 Federal, 748.

CONSTRUCTION OF LEASE OF COAL MINE

A lease conveyed to the lessee all the coal under a tract of land with the exclusive right to mine and remove the same for a period of twenty years, with the right to erect any underground entries, railroads, etc., necessary to mine and remove the coal from "said land," with the right to remove all fixtures when further mining became unprofitable; it also permitted the lessee to remove coal mined from adjoining land not embraced in the lease through the shaft located on the leased premises, upon paying a specified royalty for all coal so removed. The lease also granted to the lessee the use of five acres of the surface upon which to sink a shaft, erect buildings, railroads, etc., and contained a provision to the effect that if before the expiration of the lease the coal in the leased premises were exhausted the lessee could use said five acres so occupied to mine coal from adjoining lands upon the payment of a certain sum per acre. In an action to enjoin the lessee from using entries under the lands of the lessor to mine coal from other lands through a shaft not on plaintiff's land, the court held that under the terms of the lease, on the principle that the expression of one thing in a contract was the exclusion of all others, the lessee could not use entries under the lands of the lessor to mine coal from other land through a shaft not on the lessor's land.

Thomas Beek & Sons v. Economy Coal Co., (Iowa) 127 Northwestern, 1109. October 1910.

LEASE OF COAL LANDS TO INDIANS—REGULATIONS OF SECRETARY OF INTERIOR

The United States statute provides that the coal lands of the Choctaw and Chickasaw tribes of Indians should be under the control and supervision of two trustees, who should perform their duties under the rules as prescribed by the Secretary of Interior. It also provides that each lease should include 960 acres and be for a term of thirty years, and that the royalty should be paid on all coal produced by the lessees at the rate of 15 cents per ton, and gave the Secretary power to reduce or advance such royalty when it was to the best interests of the Indians, and required an annual payment in advance of \$100 for each of the first two years, \$200 for the third and fourth year, and \$500 for the fifth and each following year, to be treated as advance royalty and credited on royalty when any mine was developed and worked. On failure to make such payment for 60 days, any lease should be null and void, and all payments made should be the property of the Indians. Under this statute the Secretary of the Interior has no power to require lessees of such mines to mine on each lease 3000 tons the first year, 4000 tons the second, 7000 tons the third, 8000 tons the fourth, and 15,000 tons the fifth and each succeeding year, or pay the royalty on such quantity if not mined, and also prescribe that a failure to do so would forfeit the lease.

United States for the use of Choctaw and Chickasaw Nations v. McMurray. 181 Federal, 723.

McCaskey, and C. G. Yale, 308 pp.

Bristol's Ink-Type Recording Instrument

An illustrated description of Bristol's patented semi-transparent smoked-chart recorder has been previously published, and although these recorders are fundamentally simple in their construction and hundreds are in daily service, there has been a call for a recorder in which the record is made with ink. To meet the demands for a frictionless ink-type of recording instrument to parallel the smoked-chart as near as possible in fundamental simplicity and to accurately record fractions of milli volts, and adapted for use as a recording electric pyrometer, the instrument illustrated herewith has been developed and placed upon

FIG. 1.

the market by The Bristol Company of Waterbury, Conn., and is described by the company as below.

These instruments are the result of several years of study and experience with an original Bristol patented design of a frictionless ink recorder using a hinged electrical move-

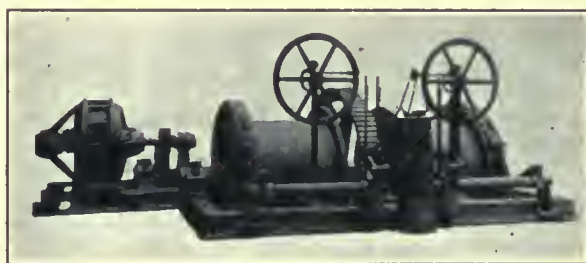

FIG. 2.

ment carrying a retaining receptacle for marking-fluid which extends over the path of the recording tip and is provided with means for periodically making contact with the source of marking-fluid and the chart. Fig. 1 is an interior view showing the galvanometer movement case hinged to the back of the instrument and carrying the inking pad in front of the recording arm. Fig. 2 shows the sensitive electrical movement swung to one side for convenience in removing the record and inserting a fresh chart. A capillary gold tube, open at both ends, is carried at the end of the recording arm at right angles to the surface of the chart. The inking pad is suspended from the case of the electrical movement and is curved to correspond with the arc covered by the motion of the end of the recording arm. When the movement is swung back into its

operating position as shown in Fig. 1, the recording arm can swing free, accommodating itself to the position corresponding to the delicate current which is to be measured. The clock which revolves the chart at the desired speed also automatically presses the inking pad toward the chart every ten seconds, bringing one end of the capillary tube into contact with the chart and the opposite end simultaneously into contact with the inking pad. A fine dot of ink is left on the chart and the capillary tube is replenished with ink from the pad. The recording tube thus carries a constant supply of ink, and its perfect balance, which is very important, is always maintained. The electrical movements used in these recorders are made especially for the purpose by the Weston Electrical Instrument Co. The instruments have been thoroughly tested in practical service for more than two years past. Although the most important applications of these recording instruments have been for pyrometers, they have also been used for electrolytic research, recording voltmeters, and recording shunt ammeters.

Nevada-Douglas Electric Hoist

An interesting type of double-drum electric hoist was built for the Nevada-Douglas Copper Co., at Mason Valley, Nevada, by the Wellman-Seaver-Morgan Co., and is illustrated in the accompanying figure. This hoist consists of two drums of 60-in. diameter with 42-in. faces. They are built with steel-plate shells, each drum running loose

GENERAL ELECTRIC HOIST OF NEVADA-DOUGLAS COPPER CO.

on the main drum shaft and being fitted with taper bronze bushings, and each having band friction-clutches and powerful band brakes. The hoist is therefore, adapted to operation either in balance or independently, as desired. Each drum has a capacity for winding 1200 ft. of 1-in. rope in two layers. The load handled amounts to 9800 lb., including skip and rope. The skip runs on a 45° incline at a speed of 400 ft. per minute. Each drum is equipped with large dial indicators for showing the position of the skip in the shaft.

As will be observed, the drums are mounted low in the frames, so that all tendency toward vibration and consequent noise is eliminated. The hoist is fitted with machine-cut gears throughout, with pinions of steel, and the motor is a General Electric motor of the I. T. C. 16-pole type, of 225 hp., wound for 2080 volts, 60 cycles, 3-phase. It runs at a speed of 430 r.p.m. The motor and hoist are securely mounted on one bed plate, the entire hoist being especially planned for severe continuous duty.

Engineering Data

One of the most interesting developments that has come about with our modern system of great industrial manufacturing combinations and immense and specialized factories, has been the production of pamphlets, bulletins, and other publications dealing with the technical applications and aspects of the company's products. A considerable amount of thought has been devoted to the preparation and distribution of this matter. Series of bulletins are arranged which cover the use of a certain mechanical unit in the different fields. Results of authenticated tests, curves, and tabulated figures are given, so that the engineer in utilizing the material may know what to expect under actual

working conditions, aside from any selection from the lists of sizes or capacities that his judgment may indicate.

It was at first undoubtedly true that these bulletins, which must not in any way be confused with house organs or publications composed mainly of interesting or self-interest reading matter, contained material that was more advertising and laudatory in its nature than replete with concise technical information. It soon became evident, however, that the engineer desired definite, concrete statistics concerning the materials and products with which he was dealing. The bulletins accordingly came to comprise more and more such specialized literature, until today they constitute a genuine contribution to the fount of knowledge of the world. The very desire on the part of the manufacturer to be able to place gratuitously at the call of actual or potential customers all available data, caused him to undertake many investigations along lines that might otherwise have been neglected or undeveloped. These researches have been conducted on a scale impossible for the individual or even the engineering schools, because of the lack of funds or time necessary. That the reasons for such endeavor are in the main selfish is undoubtedly true, but there is, nevertheless, thereby accumulated a vast amount of informing matter, and the data is usually backed by the willingness of the makers to have their engineers and experts coöperate personally and fully with the staff of the purchaser concerning any questions which may arise.

For some time the Hyatt Roller Bearing Co. has made a practice of issuing bulletins covering in detail the ratings and capacities, indicated uses, and actual application of its flexible roller bearings. Separate issues cover the different types, such as the 'Long Series' for machine tools and similar work, the 'Short Series' for automobile service, those employed in standard shafting boxes, and those for special work in cars used in the transportation of passengers, freight, and mine products. Forms for the entry of questions or specifications are also provided and, with the carefully arranged tables in the bulletins, make it easy to procure the proper bearing for the particular instance. These bulletins are at the call of any interested, and form a collection of special information worthy of a place in any engineer's office.

Sintering Fine Ore

By GEORGE W. MAYNARD

At the Wilkes Barre meeting of the American Institute of Mining Engineers, June 1911, James Gayley presented a paper entitled 'The Sintering of Fine Iron-Bearing Materials,' in which he made the following statement: "There are vast deposits of magnetic iron ores in the United States and Canada that are too low in iron for use at the present time, but which can be economically concentrated into very rich material; in many cases the fineness of crushing necessary to secure proper concentration has prevented their use except in extremely limited quantities. The reclamation of these orebodies will add tremendously to ore reserves of the United States, and this can best be done by a simple and efficient method of sintering."

The magnetite deposits in the Eastern States have their largest development in New Jersey and the Adirondacks in New York. In the New Jersey Geological Survey for 1911, the number of magnetite mines and deposits is stated to be 366, of which a relatively small percentage produces ore of high enough grade for the blast-furnace without close sorting. In the Adirondack and Lake Champlain districts there are large deposits which have been worked for many years and are still important producers of ore of high enough grade for shipment without close sorting, but the number of low-grade deposits is in excess. The occurrence of apatite, lime phosphate, formerly an unwelcome constituent in some of the large deposits, has now become a source of profit through the adoption of magnetite separation and concentration so successfully carried on at the mines of Witherbee, Sherman & Co., near Port Henry.

Granular ore in the blast-furnace is objectionable, re-

sulting in an abnormal production of flue-dust, irregular working, and a heavy loss. Of the many devices for utilizing high-grade concentrate the Dwight-Lloyd system has been found the best, as to cost, capacity of plant, and the resultant product. The process is essentially automatic and continuous, the output depending upon the regularity of feed, which in the case of magnetite will average about 100 tons per day for each machine. The working costs are embraced in power, fuel intermixed with the ore, labor, repairs, and royalty. The resultant product is a sintered cellular mass presenting an exceptionally large surface to the ignited blast-furnace gases and an increased output over compact lump ore. The results obtained in the treatment of blast-furnace flue-dust have been eminently satisfactory and have been most favorably commended by a committee from the Steel Corporation. Tests have been carried on for several weeks at the American Ore Reclamation Co.'s works at Birdsboro, Pennsylvania.

The size of the grains of ore will depend upon the mesh necessary for the separation of the gangue in the magnetic concentration. About ten barrels of ordinary capacity will usually be sufficient for a test. Apart from the freight charges the tests will be made without cost to parties intending to investigate the process. The Reclamation company will erect plants at the actual cost of erection, and will furnish working drawings. Payment will be based on a tonnage royalty during the life of the patents. Copies of Mr. Gayley's description of the process and plant will be furnished on request, together with the details of cost of plant and the royalty rates. The Birdsboro plant is open for inspection to those who wish to see the working of the machine or who may wish to have sample lots tested. Samples of sintered ore and flue-dust may be inspected at room 1908, 71 Broadway, or 20 Nassau street, New York City.

Commercial Paragraphs

The Calumet & Hecla is installing 32 of the largest sized Hardinge mills as one unit in its new re-grinding plant which is being built to utilize tailing. This installation has been made after two years of competitive trials of several Hardinge conical mills with other fine-grinding devices in the different plants of the company. The Porcupine Gold Mines Co., Ltd., better known as the Vipond Co., of the Porcupine district of Canada, has placed an order for two Hardinge ball mills to be operated in tandem with two Hardinge sliming pebble mills for its amalgamating and cyaniding plant. THE HARDINGE Co. is also shipping a 4½-ft. ball mill to the Olla de Oro Mining Co., of Bolivia, which mill will be carried over a pass in the Andes at an elevation of 17,000 feet.

An announcement of interest is that of the absorption by the PELTON WATER WHEEL Co., of San Francisco and New York, of the entire rights, including patents, goodwill, and patterns, of the Doble water-wheel business formerly conducted by the Abner Doble Co., of San Francisco. W. A. Doble, former head of the Abner Doble Co., goes to the Pelton Water Wheel Co. as its chief engineer, vice George J. Henry, Jr., who until recently occupied that position. A particularly strong combination is thus formed, as these companies have for years been recognized as the pioneers in the development of hydro-electric engineering, and the merged experience of the two companies, together with patents now controlled by the Pelton Water Wheel Co., forms an organization with the best possible facilities to cope with any problems in the field of hydraulic engineering. In addition to Pelton and Doble tangential water-wheels, the Pelton Water Wheel Co. manufactures the Pelton-Francis turbine, adapted for medium heads and large powers, besides a line of high-grade centrifugal pumps. Pelton oil pressure governors are also a feature of this company's product. The Atlantic department of the company, with offices in New York City, has recently completed large and well equipped machine shops in Harrisburg, Pennsylvania, the two points of manufacture thus facilitating deliveries to all parts of the world.

EDITORIAL

TORONTO, in place of Ottawa as first planned, will be the place of meeting of the Canadian Mining Institute, March 6, 7, and 8. Headquarters will be at the King Edward hotel.

BY ERROR in phrasing, our Mexican correspondent was made to say, in our review number, that the Amparo Mining Company continued to pay dividends at the rate of 3 per cent. The fact is that this is the rate per quarter, making the annual rate 12 per cent.

SALE of promoter's shares on a market made for treasury shares, is said to have been one of the causes of trouble at Austin, Nevada, where the Austin Manhattan Consolidated Mining Company is now in the hands of a receiver. This has been one of the most common means adopted for robbing the public and has contributed greatly to the general impression that a buyer of mining shares in the United States is inevitably a gambler.

GEOCHEMISTRY and geophysics fortunately are now attracting much attention. It is well that the border lines between the fundamental sciences be cultivated and knowledge carried from one field into another often proves surprisingly fruitful. As indicative of the demand for exact data in one of these fields, it is interesting to note that a second edition of "The Data of Geochemistry," first published in 1908 by Mr. F. W. Clarke, the chief chemist of the United States Geological Survey, has already been found necessary. The new edition of this extremely serviceable book contains much that is new and interesting.

A RECENT meeting of the Le Conte Geological Club, at Leland Stanford, Jr., University, was made the occasion for the transfer to Mr. N. F. Drake, now professor of economic geology in that institution and until recently professor of geology in the Imperial Pei Yang University, of the Order of the Double Dragon, of the third class, conferred on him by the Chinese Government in recognition of his signal service in the cause of education in the Flowery Kingdom. Americans have taken a prominent part in the educational development of the Orient, and the honor thus conferred is a pleasing recognition of disinterested service.

POSTAL FACILITIES between the United States and foreign countries are shrouded in mystery for many otherwise well informed citizens. Most people are aware that letters may be sent to England for 2 cents, but comparatively few know that the same rate applies to Germany, provided the mail goes forward on the German mail steamers. Shanghai, China, also enjoys the same rate, as a United States post-office is maintained in the foreign concession there. Enclosing return postage is often an effective means of eliciting a reply, and it should be more generally known that this can be done in the case of foreign countries by means of a coupon, purchasable at the larger post-offices, which is exchangeable for its face value in stamps in many countries of the Universal Postal Union.

GRUBSTAKING prospectors is proving popular, and, following the lead of Denver, commercial bodies in South Dakota are interesting themselves in a proposal to raise \$20,000 for that purpose. The Los Angeles Chamber of Mines and Oil has, however, decided against the proposal, taking the view that "to undertake a commercial enterprise of the kind would destroy the Chamber's prestige as a purely civic organization, and would bring it into direct competition with other development companies." The Chamber has made arrangements to file, for a small fee, descriptions and terms of sale of prospects where they may be accessible to anyone interested, but without assuming any responsibility for the accuracy of the description.

COST of living is a topic of never-ending interest in recent years, and the explanations advanced to account for its enormous increase in recent years are numerous and varied. One can be found in our national debt-habit, and it is interesting to note in this connection that the municipal debt of New York city now reaches \$1,057,811,000, or a sum \$20,000,000 greater than the national debt. This corresponds to a per capita debt of \$218, and 28% of the yearly revenue of the metropolis is required to meet the interest charges. Within five years the debt has nearly doubled, the tax rate has increased 60%, and the credit of the city has altered from better than 3% to worse than 4%. The cost of high living is an important factor in the high cost of living.

PROXIES have been sent to members of the American Institute of Mining Engineers so that those unable to attend the annual session may still register their wishes in regard to matters coming before the meeting. While the form sent out was apparently intended to cover only votes on the amendments now before the Institute, it will allow the holder of the proxy to vote as well on other matters. Since the election of officers is quite as important as any other matter, it would be well to wait until nominations are announced, as required by the constitution, two weeks before the meeting, in order that preferences in regard to officers may also be indicated. We are glad to note that a special effort is being made to secure a large attendance at the annual meeting. A circular letter signed by a large number of the most influential members of the Institute calls attention to the desirability of having as many as possible present in person, and announces that local committees have been formed in New York to arrange for a suitable program and other matters. Let every engineer who can do so, arrange to attend.

Juvenile Waters and Hypotheses

It is commonly said that criticism is easy, but an examination of criticisms would often tend to prove the contrary. Sainte-Beuve wrote reviews of contemporary publications that, as contributions to literature, were often superior to their objects. But present day book-reviewing, from the pressure of the flood of volumes to which each year gives birth, has tended toward a semi-mechanical formalism; the reviewer, after mentioning the title and the author, too often indulges in a few generalizations, commends the excellent illustrations (or some other feature), calls attention to a few typographical errors in order to show that he is both critical and impartial, and the book is reviewed! The review by Mr. A. C. Lawson, given elsewhere in this issue, is so agreeable a contrast to the ordinary one that our readers will peruse it with as much interest as they accord

the volume reviewed; it furnishes the dash of tabasco which serves to enhance the dish.

The evolution of geological concepts, conforming with a recent view of the evolution of living forms, appears to be marked by periods of increasing tendency toward variation, succeeded by periods of mutation itself. This is no less true of the conceptions of the origin of ore deposits, and geologists who do not regard themselves as being of advanced age can remember more than one swing of the pendulum of geological public opinion, as under the influence of some vigorous thinker new evidence or new methods of study have been brought to the fore, and, be it said, often over-emphasized. But this latter phase of the matter need not occasion great alarm. There is a story of Kipling's which makes an instructive comparison between a young man in the colonies, and a puppy which gnaws bones, boots, and cakes of soap with indiscriminating zeal. Though annoying at the moment the permanent result is not serious, and this may be also postulated of the younger disciples of a school of thought. Their application of a new hypothesis, like a new jack-knife, to every portion of the edifice of knowledge is not likely to result in serious damage.

It is clear, of course, that indiscriminate use of hypotheses, as well as of jack-knives, should not receive encouragement, and Mr. Lawson will find many readers sympathetic with his protest against too ready application of the hypothesis of the influence of igneous emanations in the formation of orebodies. On the other hand, it is not necessary to banish jack-knives because of the damage which can be done with them, nor it is likely that lasting benefit will accrue from the reading of a hypothesis out of the scientific communion with bell, book, and candle because of its too hasty application to diverse problems. Placing a square peg in a round hole is not profitable, but square holes are known to occur. Geology, in its early stages so largely speculative, has now resolved itself into a study of tangible phenomena—forces and their results. This being true, it is but natural that some tendency should be exhibited to deny the value of speculations when applied to cases where direct study is not possible, even though based upon well known phenomena in other fields of study, and that geologists should be slow to accept the aid of collateral evidence derived from the study of alloys, mattes, and slags, and from the astonishing advances made in our knowledge of physical chemistry within the past two decades is perhaps not remarkable.

The stricture that the doctrine of the origin of ore deposits by magmatic waters does not explain their absence along the majority of contacts may be met by defenders of the doctrine with the *tu quoque*. Why does not every fissure contain an orebody? Why does not every quartz vein, whatever its origin, contain gold? If we apply this acid test all theories are likely to be dissolved. Purely thermal metamorphism would indeed be of importance, if there were any indisputable evidence that it frequently, or ever, occurred. The available evidence of the influence of water vapor in so desiccated a process as ordinary smelting may well give rise to doubt of the possibility of thermal metamorphism in rocks containing moisture which are intruded by magmas that abundantly exhibit evidence of frequently containing large quantities of gases, among them water vapor, in solution. Finally, the puzzling problems which arise in the study of the solidification of so simple a magma, if we may so term it, as an alloy of copper and tin, involving as it does the decomposition of compounds formed at higher temperatures, reactions between solid phases, and molecular migrations, should conduce to patience with the inability of the magmatic geologist to ade-

quately explain all phenomena. Much profit has been derived from the recognition of the important part which igneous emanations have played in the formation of veins. A single hypothesis explaining the origin of all orebodies would be convenient, just as a carpenter might find it convenient to saw, plane, and drive nails with a single tool. But a variety, adapted to a variety of uses, leads to better results, and while vigorous protest against indiscriminating application of any hypothesis may be applauded, juvenile waters as well as juvenile enthusiasms merit patient consideration.

The Goldfield Report

Unusual interest attaches to the annual report of the Goldfield Consolidated Mines Company, since that fortunate corporation owns the greatest gold mine in the world, from the point of view of present production. We printed, January 20, through the courtesy of the mill superintendent, Mr. J. W. Hutchinson, full details of operating costs in the mill, and early last year Mr. Hutchinson allowed us to spread before his professional associates the intimate facts relating to the construction of the great plant under his charge. This week we reproduce, practically in full, the annual report of the company for the fiscal year ended October 31, 1911. It is an excellent report and tells a cheerful tale of a prosperous year. Mr. J. F. Thorn, the superintendent, is to be congratulated upon continued reduction of operating costs and the generally satisfactory condition obtaining. If the stock is selling for less money than a year ago, it is to be remembered that division of capital cannot be indefinitely continued. Little exploration of the deeper levels has been undertaken within the year and the new ore developed was mainly in continuation of known ore-shoots. Mr. Thorn finds, as did Mr. J. H. Mackenzie and Mr. J. R. Finlay before him, that accurate estimates of ore reserves in such a property as the Goldfield, are difficult to make and of uncertain value. Speaking in general terms, he estimates a reserve of 600,000 tons, enough to keep the mill running for two years. No attempt is made to fix the value of this ore, though it is frankly stated that the present grade, \$32.55 per ton, probably cannot be maintained. It is hoped to offset this in part by increasing the capacity of the plant. Mr. Thorn's estimate is not put forward as being based upon exact measurements of blocked ore, and is in effect but the personal judgment of a capable and conscientious engineer thoroughly familiar with the property. Presumably it has the approval of the consulting engineer, Mr. J. H. Mackenzie, though no statement to that effect is made in the report. This is to be regretted, since when so little exact data is available it is well to have confirmation of even the best judgment. We sympathize with Mr. Thorn in his disinclination to attempt blocking and estimating an ore reserve in the Goldfield ground. The advisability of undertaking extensive development, under such conditions as obtain at Goldfield, is a matter concerning which engineers differ. The policy pursued saves money to the company now, but invites unfavorable comment when, in the future, the inevitable pinch for ore comes. Mr. Thorn has done well to be frank about the matter. The public evidently accepts his judgment, since the present price of shares is about that called for by two years continuation of the present regular and extra dividends, followed by division of the surplus. The mine may prove to be worth much more than this, we sincerely hope it may, but if the orebody is of such a type and the conditions of working such as not to permit estimates of ore reserves other than as indicated, the present value of the shares

is properly low, regardless of what the future may hold for them. The Goldfield is a great mine and many excellent things are being done at the property; one of the best features of the management is the frankness with which unfavorable as well as favorable matters are discussed with the stockholders.

The Mascot Copper Company

Some two and a half years ago, August 21, 1909, we expressed editorially our opinion of the Mascot Copper Company. In response to numerous requests for information we regret to say that nothing made public since has caused us to change the unfavorable opinion then expressed, nor have we any increased confidence in the probability of a favorable outcome as regards the small investor. Despite the elaborate banquets given the stockholders, the souvenir blocks of copper distributed, the display of specimens, the energetic house to house canvass to sell shares, and the publication of letters from mayors, bankers, and ex-governors, we remain unconvinced as to the large value of either the property or the shares in the company. There is undoubtedly some ore in the mine, but how much is the question. It is equally a question how much benefit a minor stockholder is to derive from the sale of the ore. Current rumor among engineers is to the effect that development in depth has proved disappointing. How well founded this is we are not prepared to say; the point is that no one qualified to do so has made a statement. What is needed is a thorough report upon the property and the company by a disinterested and competent engineer. No recent report has been published, and the old ones, dated variously in 1907, 1909, or not dated at all, are lacking in the definite statements of facts and cogent reasoning that are demanded by the situation. The material published by the Mascot Copper Company is mere twaddle, and in no sense the sort of data rightfully expected and furnished, for example, in Mr. Pope Yeatman's report on the properties of the Braden Copper Company. Mascot stock is being sold by the methods usually adopted by irresponsible and fraudulent concerns, and its sponsors can not well object if therefore they must face the same suspicion that properly greets a fakir. The matter would hardly be worth comment except for the fact that the officers and directors of the company include, along with some men of more than doubtful reputation, others of the highest standing. They are men from whom the public naturally expects better things. It is reported that sales of stock to par value of more than \$2,000,000 have been made. Much of the money devoted to the enterprise has been supplied because of public confidence in these leaders. They owe it to themselves and to the public to make assurance doubly sure; to meet all questionings with frank, full statements of fact. What the public wants to know, and what in our judgment it has a right to know, is:

1. On the word of a competent and known engineer, after thorough examination, not a mere visit, what are the ore reserves of the property, both as to quantity and grade, and what are the probabilities, if any, of additional reserves being developed?

2. What steps have been taken to determine the proper means of treatment of the ore?

3. What is the financial position of the company, and what will be the distribution of profits, if any, between buyers of the stock now being peddled about, and the promoters?

Until satisfactory answers to these questions are made, we shall continue to recommend that investors let Mascot Copper stock severely alone.

Report of the Goldfield Consolidated Mines Company

The fiscal year which ended October 31, 1911, was the company's banner year at this great Nevada gold mine, according to the president, George Wingfield, in his annual report, not only with respect to tonnage handled and amount of earnings, but to ease of operation combined with freedom from adverse circumstances. The property has produced within the year 330,549 tons of ore of an average value of \$32.55 per ton, or \$10,760,199. Metallurgical losses of \$1.81 per ton, or \$597,071, leave a net realization from the year's production of \$10,163,127, or \$30.74 per ton.

The gross expenses of the company, including mining, milling, transportation, general, taxation local, state and federal, and all construction, have amounted to \$2,636,281, leaving a net operating profit of \$7,526,846, an increase of \$179,154 over the previous year, notwithstanding the fact that the gross returns this year were \$110,806 less than last year.

PRODUCTION AND EXPENSES, YEAR ENDED OCTOBER 30, 1911

PRODUCTION		Total Value.	Aver. Per Ton
330,062 Tons Milled		\$10,586,936.42	\$ 32.08
487 Tons Shipped		173,262.18	355.77

*Includes Laguna. **Includes Jumbo No. 2.							

With this less gross production in 1911, but with a greater tonnage handled by 63,682 tons than that in 1910, total costs have been reduced \$3.07 per ton. Construction costs in 1910 were greater than in 1911, but an elimination of construction items for both years still shows a lower cost per ton for 1911 of \$1.82. The reduction in general expenses alone shows a saving of 34c. per ton over 1910. Four dividends at 50c. per share each, or \$2 per share, were paid during the year, aggregating \$7,118,296. The company closes the year with a cash balance of \$1,369,177, and with bullion and concentrate settlements outstanding of \$451,306. The company has no debts.

Additional milling facilities are being provided at an approximate estimated cost of \$70,000, whereby large econ-

omies are anticipated in the treatment of concentrate residues. This will narrow the output to bullion alone, all by-products being handled locally at maximum economy. Depreciation of plant and equipment has been written off to the extent of \$147,195. Development work on the property during the year equaled 46,739 ft. The property holdings have been increased by the purchase of the Bullfrog Fraction at a cost of \$13,000, the Jumbo Fraction at a cost of \$2500, and a half interest in the Vinegerone Claim at a cost of \$195,000. The company's policy of distributing net realizations as they accrue, to stockholders in dividends, and retaining a cash reserve of not less than \$1,000,000, will be maintained.

MINE REPORT

The following statements by the general superintendent, J. F. Thorn, give details of production and expenses, figured on total tonnage, together with detailed cost on concentrate treatment figured on tons of concentrate only:

OPERATING COSTS

	Cost per ton.
Mining—330,549 tons.	
Labor	\$2.22
Supplies	0.99
Power	0.14
Total	\$3.35
Transportation—330,062 tons.	
Railroad operation	\$0.06
Railroad maintenance	0.03
Total	\$0.09
Milling—330,062 tons.	
Labor	\$0.43
Supplies	1.17
Power	0.29
Total	\$1.89
Concentrate Treatment.	
Labor	\$0.04
Supplies	0.32
Power	0.02
Total	\$0.38
Total Operating	\$5.71

CONCENTRATE TREATMENT COSTS

	Cost per ton.
Tons Treated—20,306.23.	
Labor	\$0.63
Supplies	5.09
Power	0.40
Total	\$6.12

Operating Results.—The stopping cost for the year was \$2.29 per ton of ore mined, and development cost was \$1.06, making a total mining cost of \$3.35 per ton. A total of 46,739 ft. of development work was performed at a cost of \$7.51 per foot. The total cost of mining and milling, which includes concentrate treatment, was \$5.62 per ton, or \$0.66 per ton less than the previous year. The total operating costs, including construction, were \$8.08 per ton, a decrease of \$3.07 per ton as compared with cost of \$11.15 for previous year. During this year the assay building, electrical building, storage-battery plant, and Laguna head-frame, which were started prior to November 1, 1910, have been completed. Improvements at the mill have also been undertaken.

Combination.—In the Combination mine 6201 ft. of development work was performed during the year, which, together with the sill floors resulting therefrom, produced 2376 tons of ore worth \$17.78 per ton, of a total value of

\$42,244. The principal new orebody in this mine is the 136 stope, 140 ft. north of the shaft on the second level, which has produced 6877 tons, worth \$88.64 per ton, or a total of \$609,602. The indications are that this portion will also be very productive during the coming year.

Mohawk.—In this mine 14,717 ft. of development work was performed, which, together with the sill floors, produced 13,203 tons of ore worth \$17.74 per ton, or a total of \$234,194. Two important new orebodies were exposed during the year. The 260 on the 350-ft. level, about 360 ft. north of the shaft, which has produced 7836 tons of ore worth \$306,397, and the 354 stope on the 450-ft. level, about 800 ft. north of the shaft, which has produced 24,566 tons of ore worth \$707,153. The 354 orebody, up to the present time, has not been found on the 350-ft. level, and its existence at that height is undetermined. It has, however, been found on the 600-ft. level of the Clermont and in an intermediate drift between the 450 and 600-ft. levels, which assures the downward continuation to a depth of 600 ft. The downward extension of the 403 orebody, 600 ft. south of the shaft on the 330-ft. level of the Red Top, was also found on the 450-ft. level of the Mohawk. Aside from these large orebodies, several smaller and very productive orebodies have been found. Also, orebodies that were known to exist in some of the caved lease workings have been uncovered and have added materially to the production of the mine. There still remains in this mine a large area, partly developed, which will undoubtedly be very productive.

Clermont.—In the Clermont 14,511 ft. of development work has been performed, which, together with the sill floors, produced 9366 tons of ore worth \$40.41 per ton, or a total of \$378,489. Several good discoveries were made in this mine during the year, the most important being the westerly extension of the 408 orebody, about 600 ft. west of the shaft between the 600 and 750-ft. levels. This stope produced during the year 27,901 tons of ore worth \$49.43 per ton, or a total value of \$1,379,071. South and above the back of the famous 401 stope on the 750-ft. level, a very promising orebody has recently been uncovered, and the indications are that it is the upward extension of the 401 orebody, having been displaced by a fault. This orebody will probably connect with 407 and 449 stopes on the 600-ft. level of the Mohawk. The development work in this orebody has produced 1668 tons of \$57.05 ore. The downward extension of the 354 stope on the 450-ft. level of the Mohawk has been located on the 600-ft. level of the Clermont, about 480 ft. northwest of the Clermont shaft, and has produced 6308 tons of ore worth \$95,433. Below the 1000-ft. level practically all development was stopped because of interference with the sinking of the Grizzly Bear shaft, which is being sunk to the 1400-ft. level. As soon as this shaft reaches the 1400-ft. level, development work on the 1200-ft. level will be resumed; only a very small block of territory at this level has been prospected.

Red Top.—In the Red Top mine 4339 ft. of development work was performed during the year, which, together with the sill floors resulting therefrom, produced 6311 tons of ore worth \$15.05 per ton, or a total of \$95,486. The downward extension of the Red Top vein is being worked from the lower levels of the Mohawk, the 600-ft. level of the Clermont, and the 450 and 600-ft. levels of the Laguna; therefore no new ore has been credited to this mine below the 330-ft. level. The orebodies on the upper levels, however, have been considerably extended, adding a large tonnage to the reserve.

Laguna.—In the Laguna, 6725 ft. of development work was performed during the year, which, together with sill floors resulting therefrom, produced 3752 tons of ore worth \$10.06 per ton, or a total of \$37,765. At this mine the downward extension of some of the Red Top orebodies has been found on the 450-ft. level, and a large tonnage will be mined during the coming year. The Hazel shaft, 420 ft. northeast of the Laguna, has been unwatered, and will be sunk to the 900-ft. level; from this point cross-cuts will be driven and a raise made to connect with the bottom of the Laguna shaft.

Jumbo No. 2.—The old Jumbo mine, which was formerly worked by lessees, has been reopened and found to contain a large tonnage of about \$15 ore. During the three months it has been in operation it has produced 3377 tons of ore worth \$67,686; 246 ft. of development work was performed, which produced 289 tons of ore worth \$10.24 per ton, or a total of \$2960. Owing to the fact that the mine has been honeycombed by lessees, it is almost impossible to estimate the tonnage. It is practically assured, however, that this mine will produce a considerable tonnage during the coming year.

PRODUCTION BY MONTHS.

Month.	Tons.	Average Per Ton.	Gross Value.
November	24,956	\$35.00	\$ 873,405.55
December	25,550	29.45	752,409.48

Ore Reserves.—Experience has shown conclusively that it is impossible accurately to estimate ore reserves in these mines, without doing a vast amount of development work at a great expense, which would be entirely useless for the purpose of economic mining. Considering the past performances of the property, the present exposure and possible extensions of orebodies now being worked justify an estimate of ore in reserve amounting to 600,000 tons, or a sufficient tonnage to keep the present mill running at full capacity for practically two years. Owing to the fact, however, that some of the high-grade orebodies have been exhausted, the value of the ore will be somewhat lower. The cost of production has been considerably reduced, which, together with the larger tonnage being milled, will make it possible to maintain a high rate of production from the lower grade of ore.

The prospect for developing ore in addition to the reserve estimated is very promising. Practically no ore has been mined, and only 500 ft. of the 4000 ft. of prospective ground along the strike of the vein has been explored below the 1000-ft. level of the Jumbo, which has produced a large tonnage of high-grade ore; therefore, the chances of finding ore at greater depth have not been nearly exhausted. The possibilities of finding new orebodies above the 1000-ft. level are very good. During the year 1911 the 354, one of the largest orebodies ever discovered in this property,

was found on the 450-ft. level of the Mohawk. Other important discoveries were made on the 150 and 350-ft. levels of this mine. A very important discovery was also made on the 130-ft. level of the Combination mine. Therefore, it is reasonable to expect that the large partly developed area above the 1000-ft. level will produce a large tonnage of new ore during the coming year.

MILL REPORT

The mill superintendent, J. W. Hutchinson, reports that the new refinery was completed and in operation January 1, 1911, and has fulfilled every expectation. The cost of refining the bullion has been reduced to 7c. per ton, as compared with 19c. per ton the two previous years. The total saving to the company made by the new refinery will be in excess of \$60,000 per year. During the year a new plate-room was built, in order to localize the work of amalgamation. A small testing plant and laboratory has also been added. Many minor changes have been made, causing the plant to handle a larger tonnage than previously, and it is expected that it will average 950 tons per day during the coming year. A plant to treat the residue from the present concentrate treatment is now in process of construction. Two Edwards duplex roasting furnaces, with 112 by 13-ft. available hearth area, and one Baker cooler, will be housed in a steel building erected for the purpose. One 5 by 18-ft. tube-mill, together with tanks, agitators, and accessory equipment will be housed in an extension to the present concentrate treatment plant, together with the necessary dust-chambers and storage-bins. The plant will cost approximately \$73,000, and will effect a saving to the company of approximately \$80,000 per year. During the year the mill ran 96.37% of the total time, and averaged 9.39 tons per stamp actual running time.

SECRETARY'S REPORT

The report for the year made by the secretary and treasurer, A. H. Howe, shows that during the fiscal year ended October 31, 1911, the issued stock of the company remained at the figure established on September 1, 1910, namely, 3,559,148 shares. The fiscal status of the company during the year has been singularly free from complication or unusual features. The total earnings for the year have been \$9,890,028.67. Deducting therefrom gross expenses of \$2,510,377.61, which includes construction expense of \$137,831.13 and depreciation of plant and equipment of \$147,194.98, leaves a net realization for the year of \$7,379,651.06. Four regular dividends at the rate of 30c. per share each, and four extra dividends at the rate of 20c. per share each have been made within the year, aggregating \$7,118,296. Stockholders have been notified that the issuance of the company's report for the fiscal year ended October 31, 1911, would be delayed owing to the necessity of rearranging accounts to conform with requirements of the United States Government. In explanation of these changes it should be said that under the Act of Congress approved August 5, 1909, and popularly known as the Federal Corporation Income Tax Law, depreciations in the value of property are made available as a deduction against gross income; but the Internal Revenue Bureau of the Treasury Department, having in charge the administration of that law, requires all depreciations so claimed to be shown on the books of account and balance sheets of the corporations claiming the benefit thereof. The methods prescribed for ascertaining such depreciations make necessary the adoption of an estimated unit of depreciation ascertained by reference to the cost of the property subject to the depreciations in question.

A complete account of the computation made necessary in this case could only be accomplished by too extended explanation. Avoiding, therefore, unnecessary detail, it may be briefly stated that the unit here employed for that purpose, in obedience to the requirements of the Treasury Department, is \$16.36 per ton, being the estimated average cost per ton to the company of its whole estimated commercial tonnage.

The theory upon which these depreciations for exhaus-

tions of ore are based is the well-known economic principle which has in numerous cases received judicial recognition and approval, and which should always be borne in mind by investors in mining property, namely, that unlike most other business projects, the earnings of a mine distributed in dividends are chiefly derived from exhaustions of the mine property in which the capital has been invested. Therefore, no matter how profitable the investment may prove to be, the dividends should not be regarded as profit in the ordinary acceptance of that term until the net amount realized shall have equaled the capital investment in the mine property. It will be observed that by reason of the adoption of a depreciation unit, as required by the United States Treasury Department, it necessarily results that the net realizations in any year from the company's operations may be derived in part from exhaustions of assets and in part from apparent profits accruing from a net recovery per ton in excess of the estimated cost per ton.

The combined cash balances of the companies at the close of the year were \$1,369,177, with bullion and concentrate settlements outstanding of \$451,306, and, excepting invoices for the current month, the companies have no debts. In response to numerous inquiries received by the office, there is given below a statement showing dividends to date:

No.	Date.	Rate per Share.	Amount.
1	October 25, 1907	\$0.10	\$ 353,247.10
2	November 25, 1907	0.10	353,377.30
3	April 30, 1909	0.30	1,066,280.10
4	July 31, 1909	0.30	1,067,364.60
5	October 30, 1909	0.30	1,067,594.10
6	January 31, 1910	0.50	1,779,549.00
7	April 30, 1910	0.50	1,779,574.00
8	July 30, 1910	0.50	1,779,574.00
9	October 31, 1910	0.50	1,779,574.00
10	January 31, 1911	0.50	1,779,574.00
11	April 29, 1911	0.50	1,779,574.00
12	July 31, 1911	0.50	1,779,574.00
13	October 31, 1911	0.50	1,779,574.00
		\$5.10	\$18,144,430.20

Taking advantage of a reduced express rate which effects a saving of approximately \$10,000 per year, the company's bullion is now being marketed at the United States Mint at Denver. A combined profit and loss statement of the Goldfield Consolidated Mines Co. and the Goldfield Consolidated Milling & Transportation Co. is given below.

COMBINED PROFIT AND LOSS ACCOUNT, GOLDFIELD CON. MINES CO. AND GOLDFIELD CON. MILLING & TRANSPORTATION CO.

Earnings:			
Ore Shipments, gross	\$ 173,262.18		
Transportation, Treatment and Charges	17,103.92	\$ 156,158.26

Types of Ore Deposits—A Review

By A. C. LAWSON

The editor of this book* is also its reviewer, and has published his review under the caption of an introduction at the beginning of the volume. The volume is a collection of papers, most of which have been published before, by Bain, Buckley, S. F. Emmons, Hatch, Hershey, Irving, Kemp, Lane, Leith, Penrose, Rickard, and C. H. Smyth, Jr. It is a very readable and instructive book albeit it has no plan or guiding principle. One might cavil at the title, but its ineptness is offset by the fact that it is a very attractive and saleable one, and readers will be pleased to discover that there are only as many types as there are authors of the book.

In his review in his book the editor very cleverly summarizes the salient points of the various essays, but quite naturally he does not do so in a critical spirit. He is optimistic and complimentary. He is in good company, and he knows it. It would mar the occasion to dissent from the views of his collaborators, so he abstains from dissent and agrees with all thirteen of them. Whether the authors would all agree with one another is not quite so clear. We might, it seems, get quite different answers from them to the question, What constitutes a type deposit? Are certain deposits types of a class independent of the fluctuating hypotheses of their genesis, or is a settled knowledge of the mode of origin a necessary factor in the definition of a type? Most of the papers are descriptions either of particular deposits or of deposits which characterize particular regions, and in these the genesis of the ore is the matter which concerns both the author and reader most. Irving's paper on 'Replacement Orebodies' is more general, and is perhaps the most successful characterization of a type; although it may well be urged that replacement phenomena may be observed in deposits of different types. Emmons' paper on outcrops, and Penrose's on 'Some Causes of Ore-Shoots,' are also of a general character, but they are really addenda to the book and quite academic in treatment. These last three essays offer such a marked contrast in treatment to the more concrete and stimulating discussions of the first ten that they might well have been reserved for a volume of different scope. They have the merit of summarizing and formulating our knowledge concerning certain phenomena of ore deposits and will undoubtedly be welcome to a large number of readers.

Turning now to the essays of most interest, the first one, by C. H. Smyth, Jr., on the 'Clinton Type of Iron-Ore Deposits,' is an admirably fair and clear discussion of the genesis of what is perhaps the most remarkable and mysterious iron ore. The author presents a strong and sustained argument in favor of the view that these ores are due to primary precipitation of iron salts from sea-water as against the hypothesis of subsequent replacement of limestone by iron salts through the medium of ground water. In his point of view, it is evident, the Clinton iron ore as a type is defined in terms of primary deposition. But those who hold the other view, which makes the ore a secondary product, would cite the Clinton beds as a fine type of replacement orebodies. So that here is the same ore deposit serving as an example of two contrasted types! If a type is to be defined in terms of genesis it must in the present state of the science be defined in terms of hypotheses, and these, as we all know, are unstable. Smyth's argument would be stronger, I might almost say convincing, if he would explain the extraordinary excess of iron in the Clinton sea which his hypothesis postulates. This question he sets aside

as extra-geological. The trouble with this is that our minds are not strictly geological, and in studying such questions they wander afield into the pleasant and wholesome domain of common sense. We naturally and properly balk at accepting a geological doctrine as satisfactory that leaves a large question unanswered, even if that question be not strictly geological.

The questionable propriety of defining types of ore deposits in terms of genetic hypothesis is even better exemplified in the second essay, by Leith, on 'The Lake Superior Type of Iron-Ore Deposits.' Here the type involves two hypotheses, one to account for concentration of the ore deposits from a lean 'iron formation,' and the other to account for the original deposition of the latter. The first hypothesis, in so far as it applies to the concentration of the iron ores of the Animikie, is very satisfactory and will doubtless find wide acceptance, particularly by those who have read Leith's more extended monograph on the Mesabi ore. But it is not at all clear from any points set forth in the paper or in Monograph LII of the U. S. Geological Survey, of which it is a summary, that the same hypothesis explains the concentration of the Keewatin ores, or the ores at the contact of the Keewatin with overlying Archean sedimentary rocks. The paper loses something of its force in its effort to generalize so broadly as to include the Animikie and the Keewatin ores in the same category. In applying his hypothesis of concentration to the Mesabi ores of the Animikie, one would like to have seen some credit given to J. E. Spurr for his earlier statement of the hypothesis. Spurr's identification of greenalite as glauconite is a very minor matter. Apart from that he clearly expounded years ago the process of concentration of the Mesabi ores in its essential features as now set forth by Leith, who makes no reference to the earlier work.

The second hypothesis is a substitution for others that have been previously entertained to account for the 'iron formation' from which the ores are derived by concentration. Briefly stated, it supposes that the iron formation is an original chemical precipitate on the bottom of the ocean of salts emanating in some aqueous or gaseous form from contemporary submarine lavas, notably ellipsoidal basalt. The hypothesis postulates the submarine origin of ellipsoidal basalt, the ellipsoidal structure being assumed to be due to extravasation under the sea. This assumption is erroneous. The most typical ellipsoidal basalt to be found anywhere occurs in splendid exposures in the city of San Francisco and at many other localities in the Coast Ranges of California and they occur as intrusive rocks; so the ellipsoidal structure is not due to submarine extrusion as Leith believes.

Another unfortunate feature of the hypothesis to some of us who are familiar with Lake Superior geology is that ellipsoidal lavas are not known to occur in the Animikie of the Mesabi range where the 'iron formation' in question is best exemplified. Such rocks are abundant in the Keewatin, but these are geologically far removed from the Animikie, however closely they may be associated geographically. Just what submarine lavas gave rise to the supposed emanations that were precipitated as the 'iron formation' of the Mesabi range? Are the Mesabi iron ores typified by the formation of so precarious a hypothesis?

It is a pleasure to read the third and fourth papers, by Bain and Buckley, the one on the 'Flats and Pitches of the Wisconsin Lead and Zinc District,' and the other on the 'Lead and Zinc Deposits of the Ozark Region.' The pleasure arises not only from the lucid and convincing style of both authors, but also from the fact that here at least we escape the prevailing obsession regarding the efficacy of juvenile waters, to which, as we have just seen, even the Lake Superior iron formations have succumbed. Bain's paper

*Types of Ore Deposits, edited by H. Foster Bain, with chapters by H. F. Bain, E. R. Buckley, S. F. Emmons, W. H. Emmons, F. H. Hatch, O. H. Hershey, J. D. Irving, J. E. Kemp, A. C. Lane, C. K. Leith, R. A. F. Penrose, Jr., T. A. Rickard, and C. H. Smyth, Jr. 378 Pp., Ill., Index. *Mining and Scientific Press*, San Francisco, 1911.

deals primarily with certain interesting structural features which have determined in part the position of the ore-bodies and the type is defined in terms of structure. His discussion of the genesis of the ore is a subordinate matter, but in this he is in agreement with Buckley. Both authors regard the lead and zinc ores of the regions described as due to concentration from overlying sediments, and both support this view by argument so cogent that little more remains to be said. Both discussions of the questions of genesis may be taken by students as fine examples of geological demonstration; and it is noteworthy that we have as yet no equally clear proof of the deposition of ores by magmatic waters. The chief merit of the papers is not that they originate the doctrine of genesis by descending waters for these deposits, for that is an old hypothesis, but rather that they are quite convincing as to the correctness of that doctrine.

The next paper, by Lane, on 'Native Copper Deposits,' is not the description of a type, but the statement of a hypothesis accounting for the presence of native copper as the chief ore in a deposit of any type. Lane supposes copper to have been leached from basalt as chloride and to have been precipitated in alkaline sedimentary rocks which owe their alkalinity to their deposition as continental or desert formations. The hypothesis is plausible, but not any more so than Steinmann's explanation of the occurrence of copper at Corocoro.

S. F. Emmons' paper on the Cobalt district is chiefly interesting as a summary of the evidence in favor of the view, which had previously been expressed, that the rich silver deposits of that camp are the product of a process of secondary enrichment due to the descent of salts of silver from upper parts of veins now removed by erosion, and their precipitation as native silver in the lower parts. Why the bottom of the zone of enrichment is coincident with the base of the Huronian or with the base of the diabase sill intrusive in both Keewatin and Huronian is not explained. The acceptance of the doctrine of secondary enrichment does not rob Cobalt of its problems. J. B. Tyrrell's interesting suggestions as to the origin of the fissures at Cobalt are not mentioned, although they have an important bearing on the question of the former upward and the present downward extent of the veins. The Cobalt veins should be regarded as variants as to mineral contents from the ordinary fissure vein rather than as the type of these; and it is pretty clear that Emmons himself in writing the paper had no intention of defining a type.

Hershey, in the next paper, on the 'Geology at Treadwell Mines,' refers to the deposits on the Gastineau channel as the "type par excellence of a large low-grade gold-quartz deposit." But the type appears to be based upon mining rather than upon geological considerations. As usual, he contributes new facts to those recorded by previous observers and throws new light upon the geology of the region, although the genesis of the ore remains a speculative question. The recognition of the fact that part of the slates of previous writers is the sheared margin of the gabbro, and that the latter was intruded into the sedimentary rocks before the intrusion of the ore-bearing dykes of soda syenite, appears to be based upon sound observations. It is not so clear that the light and dark facies of the soda syenite (albite diorite) are distinct intrusions, especially as the ore is practically confined to the light colored rock and the mineralizing action might well be responsible for the bleaching of the dark rock. Hershey's suggestion that the gold is derived from the gabbro is quite as good as A. C. Spencer's that it is derived from magmatic waters. But the allurements of the juvenile water hypothesis are evidently too many for him, since, although he doubts that such waters supplied the gold, he concedes that they may have abstracted the gold from the pre-existent gabbro and deposited it in the crushed soda syenite.

'The Saddle Reef,' by T. A. Rickard, is an old story skillfully retold in a form that will be very useful to students and acceptable to teachers of economic geology. From a structural point of view the saddle reef is a well defined type, and the paper is chiefly a description of the various

features exemplified in the Bendigo field. The abundant illustrations are a welcome feature of the paper. Little is said of the genesis of the deposits, but in the last paragraph we find reference to "the irruption of mineral-bearing solutions propelled by steam" as a sequel to the intrusion of few small dykes, from which it may be inferred that even this sagacious author is smitten with the juvenile water affliction.

In Kemp's paper, on 'Contact Deposits,' we have the argument for the efficacy of magmatic water in ore deposition set forth by one of its ablest and most insistent exponents. This doctrine is so important, if true, and the tendency to accept it so widespread, that its exposition is the one paper of the symposium that above all others invites criticism. In his preliminary discussion of metamorphism in general Kemp fails to make any distinction between (1) purely thermal metamorphism wherein the changes in rocks adjacent to an intrusive mass are due to molecular mobility induced by heat alone, and (2) reactionary metamorphism wherein the changes are due to reaction between the enclosing rocks and the materials emanating from the intruding mass. From his remarks it is clear that he regards all contact metamorphism as reactionary, which is a very questionable proposition to start with.

The main body of the paper is a skilful weaving of fact and hypothesis, which, however, are not difficult to segregate. The facts are chiefly citations of cases where ores are known to exist at or near the contact of limestone with igneous intrusions. With these ores are associated the lime silicates and notably the lime-iron silicate andradite. Kemp very properly points out that many of these silicates, particularly andradite, cannot be regarded as due to the crystallization of the limestone without the addition of materials which were not originally present in it. He concludes without question that these materials were derived from the intrusive magma and were carried in solution by waters expelled from it at the time of its crystallization. The next step is easy. If the lime and lime-iron silicates have thus been supplied by magmatic waters with the silica and iron which made their formation possible, then, of course, the associated ores have been deposited by the same waters. This is the case in brief for the doctrine of ore deposition by magmatic waters.

There are some minor difficulties, such as the abundant occurrence of the ore in question, both disseminated and in individual bodies, in the igneous rocks in such a way as to leave no room for doubt but that the rock was solidified before their deposition. These difficulties are not fairly met by a passing suggestion that such intra-intrusion ores may have come from magmatic waters given off deeper down where the rock remained molten. Every such case demands particular and detailed observation and discussion before we should be called upon to accept the suggestion as the true explanation of the origin of the ores. As they stand, such cases negative the doctrine.

There are also major difficulties, such as the fact that ore at the contact of acid intrusive and limestone is an exceptional occurrence. There are innumerable such contacts where no ore occurs. The doctrine of magmatic waters as advocated by Kemp should explain the absence of ores of iron and copper at the great majority of such contacts. But the doctrine is silent on this point. But even if these difficulties and others were overcome the doctrine remains feeble and can never attain to the dignity of a scientific theory until it disposes of another possible means of accounting for these ores, which has even greater claims to our attention than the supposed magmatic waters. The means I refer to is the ordinary ground water as affected by igneous intrusion. The circulation of the ground water would in every case be profoundly disturbed by the injection of hot igneous magmas into sedimentary terrains. The disturbance would, however, be far from chaotic. The presence of the hot body would be the controlling influence in determining the circulation. The circulation would always be upward on the periphery of the hot mass. This would be true not only while it was still molten, but also long after it has solidified. Such a circulation of the

heated ground water would be quite competent to do all that is ascribed to magmatic waters, including the formation of lime-silicate zones. It would not only bring to a zone of active chemical reaction the materials leached from the surrounding regions, but it would attack the still hot though solid igneous mass itself and abstract from it part of its metallic constituents. And it is significant in this connection that most of the igneous rocks that have ores either on their periphery or within their mass have been subject to very severe chemical attack. Until this very probable means of ore deposition at the contact of limestone and igneous rocks has been disposed of the doctrine of magmatic waters is unnecessary. It remains at best a possibility, one of the fashionable vagaries of our time, not entitled to serious respect as a scientifically established theory.

Hatch's paper on 'The Conglomerates of the Witwatersrand' is an excellent description of the famous gold deposits of the Transvaal. The sketch of the geological history and structure of the Rand, with its illuminating diagrams and maps, will be a most welcome and convenient source of information to American students who cannot readily get access to the earlier scattered papers dealing with the same subject. The paper also discusses the vexed question of the origin of the gold and shows very clearly that the gold is epigenetic.

Gold Mines of Mysore

By HERBERT A. CARTER

The gold mines of Mysore have long been famous. The existing industry dates from 1878, when a few enterprising individuals, among whom was General de la Poer Beresford, acquired a lease of ten square miles of country for mining purposes. This tract included what are now known as the Kolar goldfields.

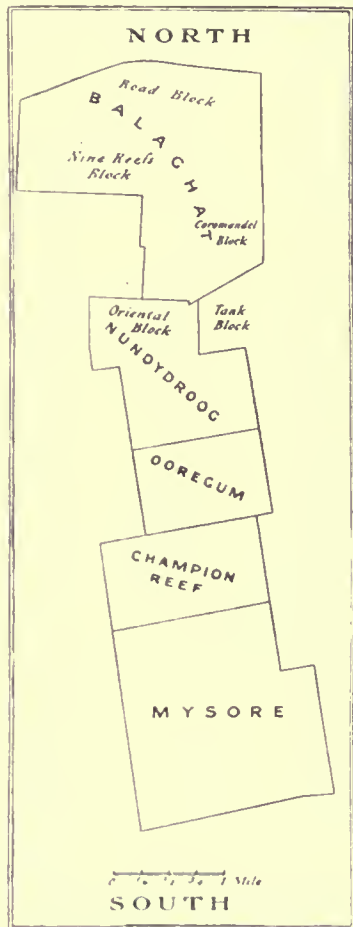

The researches of the Indian Geological Department have shown that nearly one-fourth of the whole area of the province, or nearly seven thousand square miles, is made up of Dharwar rocks, the auriferous rocks of India. Three great bands of these rocks stretch across the country from north to south. The most westerly of these cover the east flank of the Western Ghats from Banavasi, in the extreme north of the province, to Hunsur in the south. This part of Mysore being covered with dense forest, little prospecting work has been done. Old native workings have been found at Ikkeri, Bednur, Behur, and Hunsur (Kempenikote). The second of these bands, which is called the Shimoga band, extends from the Thungabhadra river on the north to Nanjangud in the south. This is the largest and best defined of the bands, and covers an area of four thousand square miles, which has been the seat of numerous powerful dynasties, with large and flourishing capitals. The ruins of palaces and temples, in which are to be seen some of the most elaborate stone carvings in the world, are evidence of the enormous wealth of the kings at whose expense they were erected. The state geologists have found many old gold mines worked by the ancients in this belt. A few English companies are now engaged in testing portions of this belt, and good veins are said to have been discovered some ten miles south of the town of Shimoga.

The third belt runs across the centre of the state from Harihar, on the north, through Kunigal, and on to the Cauvery Falls at Sivasamudram. Here also many old gold mines are indicated on the geological map of Mysore, but little or nothing has been done by Europeans to test their possibilities.

In addition to the three great bands of auriferous rocks already named there are numerous small outliers of Dharwar, scattered all over the province, showing that at one time the whole country was one great goldfield. Eons of denudation have washed away thousands of feet in depth of these rocks, and what are now to be seen are merely portions of the Dharwar series, filling the valleys of primeval Mysore. The Kolar goldfields are in one of these small outliers of the Dharwar rocks, situated about 40 miles

east of Bangalore. Up to the end of 1909 the Kolar goldfields had yielded £38,600,000 of bullion, and paid dividends amounting to £13,000,000. It is possible to form an estimate of the size of operations on the mines at Kolar, where it is stated that 600 Europeans, 400 Eurasians, and 31,000 natives are employed on the different works, and they are paid 7,500,000 (75 lakhs) of rupees in wages annually, or more than one-third of the entire revenue of the Mysore state.

The deepest workings are on the Ooregum mine, where Taylor's shaft had attained a depth of 4010 ft. at the end of 1910. There are several shafts on the field more than 3000 ft. in depth. The Kolar goldfield is 2800 ft. above sea-level. The Mysore gold mine is the chief gold producer at the present time. The return from this mine for 1909

KOLAR GOLDFIELD.

was 228,000 oz. valued at £900,000. There has been, however, a steady decrease in the richness of the ore as greater depth is reached, as will be seen from the following statement of returns:

	Tons yielded.	Ounces.
1886	6,000	15,000
1891	38,000	58,000
1896	64,000	108,000
1901	127,000	164,000
1906	185,000	205,000
1909	234,000	228,000

Near the surface the ore yielded 2½ oz. per ton; at 3000 ft. below the surface it yields less than an ounce. The profits for last year amounted to 70 lakhs of rupees, and the royalty paid to the Mysore Government for the lease of the mine was 6½ lakhs of rupees. The land is owned by the Mysore Government, which leases it out to various companies for a term of 30 years on a payment of 7½% on the annual profit. The branch line of railway from Bonringpet to Marikupam, ten miles, was built by the Mysore Government for the benefit of the gold mines, and it pays a dividend of 10% per annum. The Mysore G. M. Co., Ltd., pays dividends of 35 to 45% per annum.

Labor and Superintendence on the Gold Coast

By DONALD F. FOSTER

The frequency of comment on the inefficiency of the native labor and the carelessness of the white overseer on the Gold Coast is my excuse for the following remarks. At the outset I may as well state that during the time I was employed on the Coast I failed to note that carelessness which is popularly supposed to be the distinguishing feature of the Gold Coast mining man. On the contrary, I found that he would compare favorably with his mining brethren in any country, notwithstanding the fact that he has a bad climate to contend with and has not only to do his work, but also has to teach and set an example to the natives.

It is only in recent years that the native has been accustomed to anything like organized labor. There is the story of the engineer who, some twelve years ago, introduced the wheelbarrow to the native. The native filled the barrow with dirt, called a comrade or two, hoisted the barrow upon his head, carried it to the dump, dumped the dirt, and with the assistance of a friend replaced the barrow on his head and returned, smiling. There are now native clerks, artisans, miners, and laborers who have been taught their work by white overseers. I must not forget the work of the missionaries. Some of their work has been good, but I do not think the policy of teaching the native to believe that he is as good, if not better, than the white man, a good one. The mining man on the Coast, before he can be engaged, has to pass a medical examination in London which is more stringent than that necessary to join either the army or navy. He must also have good references as to character and ability. These precautions are good and necessary, but the man who comes in close contact with the native must, besides being competent to do his work (for there is none quicker than the native to note a man's ability), be able to teach the native, and this teaching requires patience and common sense. I have shown a 'boy' half a dozen times how to do a thing, and the seventh time he has made a bigger botch than at the first attempt. I have called him several names reflecting on the chastity of his mother and the constancy of his father, finishing up with asking him if he would ever learn. He answered me in native dialect to the effect that I had better give him a good 'hiding', and it would help him to remember, as in future when he went to do similar work he would remember the 'hiding' and be more careful. (Note: I complied with his wishes.)

The white man on the Coast is representative of almost every mining country; he comes from Great Britain, America, Australia, India, south and other parts of Africa. There are also some Germans and Italians, the majority of them having received their training in other countries where they have had to do their own work. In West Africa the white man who overworks is usually buried or invalided home, as it is impossible to do manual labor in that country without dearly paying for it.

One of the obstacles of the newcomer to the Coast is the broken English as it is spoken by the native. I have had much enjoyment from the conversation between a newcomer and a native. The following is an example of one of the most frequent occurrences: The white man is not certain that a boy has done a job that he has been told to do, so he questions the boy: "You no do that job?" "No, sah." "Well, you go do him." "I do him, sah." "Just now you say you no do him." "No, sah; I say I do him, sah." After this the white man is more puzzled than before, so he goes to see if the work is done, saying all sorts of nasty things about natives and the Gold Coast in general.

The native is not a quick learner, and once he has learned to do a thing one way it is hard work to teach him that there is a better way; he invariably answers: "My old massa do him this way, sah—he sabe too much,

sah." Which, to say the least, is very annoying. Sometimes one engine-driver likes to keep half a glass of water in the boilers—perhaps the next, an inch. If it ever happens that these men change boys there is trouble, as each white man has to teach the boy over again. Personally, I have had experience at two mining properties on the Coast—the Ashanti Goldfields Corporation, Ltd., and at Bibiani, Ltd. I have nowhere met more competent men than those employed by these companies. At Obuasi, the management of the Ashanti Goldfields Corporation, Ltd., has offices, mines, and reduction works. The consulting engineer had a tough problem to face when he took over this group of mines, and deserves great credit for making a dividend-paying mine out of the wreck that had been made by injudicious management. One of the mines was blessed with graphitic walls, and great care was necessary with the timbering; this in a country where there is no good mine timber. The ore is refractory, being a graphitic quartz containing sulphides. The former method of treatment was to wet-crush in stamp-mills, amalgamate and cyanide the sand, the slime being run to waste. The cyanidation of the sand was anything but a success, an extraction of about 30 to 40% being obtained. The mill is now used to treat ore from Justice's Find, the ore being crushed in the mill, sand and slime being separated, sand being leached with cyanide, and the slime being filter-pressed after agitation, an extraction of 90% being obtained. The refractory ore is crushed in ball-mills, roasted in Edwards furnaces, cooled and trammed to cyanide vats where it is leached with cyanide solution, the extraction being over 90 per cent.

The natives at Obuasi had never seen a ball-mill, roaster or filter-press before, and had to be taught how to look after them. This they do successfully. At times, owing to ill health, shiftmen are short and the plant has to be run with one white foreman and native shift bosses. This could not be done if the natives were as inefficient as some writers would have us believe. Nor can the white man be so careless.

According to published accounts, the average cost of mining and treatment-costs on the Rand mines is 24s. (or \$5.76) per ton. The total Ashanti costs, including London office and traveling expenses for the white staff, were for the months of July, August, and September of last year, 31/10.5 (\$7.65), 32/4.6 (\$7.77), 33/2.2 (\$7.96). The traveling expenses of the white staff will probably be 8 pence (16c.) per ton. The railway freight on materials is from £2 (\$10) to £10 (\$50). Thus taking everything into consideration, I think these costs are reasonably low.

Here are a few of the set tasks of the natives. About 3000 tons of sand had to be handled twice by 25 boys in a month. First to transfer from the collecting to the treatment vat, afterward from the treatment vats to the dump by means of cars. They had also to keep the tram lines and dump in order. The actual filling and emptying cost 5.04 pence (10c.) per ton. This is pretty cheap for manual labor. On the dry-crushing plant the cost was slightly higher; 120 tons of crushed and roasted ore being cooled (that is, damped and cooled enough to handle easily) and dumped into the vats by 20 boys, who received an average of 1.9 (42c.) per day. The cost per ton was 3.33 pence (6.66c.). The emptying of these vats was done by 16 boys who were paid 1.6 each. The cost of emptying and filling costing 5.73 pence, or nearly 11.5c. per ton. One shift-boy and helper does all the pumping and making up of solution, the white shift-boss telling him how much cyanide to add. Some of the boys are quite capable of testing and making the cyanide solutions up to proper strength without aid from anyone. One native attends to five No. 5 ball-mills. Another attends to the oiling of the dry-

crushing plant. There is a fireman to each Edwards furnace. One white man and four natives constitute a 50-stamp mill gang, where the plates have to be dressed twice a shift. I have seen a broken stem repaired and the battery running in thirty minutes with one of the gangs.

Owing to ill health my stay at Bibianaha was short. When I was there the mill was a beautiful specimen of the sectionalized stamp-mill, with a huge notice pasted up giving full instructions how to run a stamp-mill. This notice had been put up by some former manager and it was a source of much amusement to me.

The mine is three to four days journey from the railway. Everything has to be carried in by natives; the usual load being 60 lb. However, the manager brought in new mortar-boxes the sole-piece of which was cast in one piece, the upper part being cast in another which fitted into the sole-piece. These were a great improvement over the other sectionalized boxes that were in use. I do not know the weight of these pieces, but they were carried in by about thirty boys to each piece. The mill was of 55 head of stamps; being of three different makes and three different drops, times of drop, and weight. A shift consisted of one white man and six natives; the plates being cleaned twice a shift and about 6500 tons per month being milled. However, the tonnage crushed for July, August, and September last year

administer a good flogging before obedience is obtained. Once put in their place they are good workers and are employed as artisans and laborers. The Wangaras are the carriers on the Coast and take the place on the Gold Coast that the mule does in the mountain districts of Mexico. As a rule these boys are very tall. They make excellent gangs for shifting heavy machinery.

The native laborer on the Gold Coast may have been in the past inefficient, but it cannot be said with truth today. Every year he is getting better, and it would not surprise me if he takes the place to a large extent of the white shift-boss in the near future. The white man who went to the Coast a few years ago went there not to see how much he could do for his employer, but to see how much he could do him. Today it is different. Much more is understood of the illnesses that are likely to be contracted on the Coast, and the ways of dealing successfully with them. A better class of mining man is being sent out, and nowadays it is necessary to know one's work, and the mere fact of being a friend of a director does not count.

Potash-Bearing Rocks in Wyoming

The Leucite hills of Wyoming, in the Rock Springs coal district, have long been known among geologists as interesting examples of volcanic outflows of an unusual lava. They now assume possible economic importance as a source of potash to meet, in part at least, the steadily increasing demand for this fertilizing material, for which the United States must now look to Germany. The announcement that a Western company intends to erect a plant in the Leucite Hills area for the extraction of potash and alumina from these rocks makes opportune a report recently issued by the U. S. Geological Survey describing the character and distribution of this lava formation and estimating the amount of potash and alumina it contains. Assuming that the process intended to be employed proves commercially feasible, it is highly interesting to note that the Survey places the potash content of the leucite rock 'in sight' at 197,349,617 tons. This estimate is based on a careful geological examination of the area and a series of analyses of the rock, which show an average potash (K_2O) content of over 10 per cent.

During the past 30 years Survey geologists have studied and described in their reports these lava deposits, so that the present brief report by Whitman Cross and A. R. Schultz is simply a realization on the earlier regular geologic work of the Survey. An examination of the area was made by Mr. Cross in 1884, followed by a careful study, describing in exact terms these exceptional rock types, which at that time held only scientific interest. In 1907 and 1908 Mr. Schultz, who was engaged in Government coal-land classification work in the Rock Springs area, made incidental observations of these igneous rocks, and only the press of other work prevented his publishing before this time a scientific contribution on the area which has now come to have economic interest and possible value to industrial chemists who are attacking the problem of furnishing an American potash supply. Should this feature of the potash situation be worked out successfully, the potential value of the Leucite hills would of course be large.

THE THREE WESTERN OFFICES of the Mineral Resources division of the United States Geological Survey, at Denver, Salt Lake City, and San Francisco, have all been moved to new quarters during the past year. The Denver office, at 311 Chamber of Commerce building, is in charge of Charles W. Henderson; the Salt Lake City office, at 825 Kearns building, is in charge of Victor C. Heikes; and the San Francisco office, at 305 United States Customhouse, is in charge of Charles G. Yale.

NEW PLANT AT OBUASI.

was 7864, 8516, and 7742, respectively. Taking 18 boys at an average cost of 1/6 per day each, the cost per ton for native labor is 1.14d. (2.28s.), 1.05d. (2.10s.), and 1.12d. (2.24s.) for crushing and amalgamating. This mill was fitted with Hoscour feeders, and I have no doubt that had it been fitted with Challenge feeders, four boys per shift would have been ample.

Perhaps a few remarks on the native laborers will not be amiss. The Fantis are the most numerous and are engaged in all classes of work, skilled and unskilled. Some of them have been to England and taken a mining course in a school of mines. The majority of the clerks are Fantis, as are also the native artisans. The Accra and Gold Coast Castle boys are, in my opinion, the best of the Fantis. The Ashantis are about as lazy workmen as it is possible to find. However, the Ashanti steward boy is possessed of a rare virtue among natives; he is fairly honest and does not, as a rule, steal from his employer. The Ashanti women are good workers, especially on task work. The average weight of sand a 'mamie' will carry is 60 lb., but on special occasions I have known them to carry 100 lb. These figures have been taken from a large number of weighings. From a labor standpoint an Ashanti and a Fanti 'mamie' are equal. The Lagos boys are the best unskilled laborers on the coast. Many white men do not like them because they object to being hit without reason and hit back. A Fanti can be hit with or without cause, and he does not worry. Some of the Lagos boys are good air-drill operators and some are engine drivers, but the majority are shovelers, trimmers, or firemen, in which they excel all other natives. The Kru boy is useful, but in most cases it is necessary to

The Statement of Working Costs

By A. W. ALLEN

The cost of treatment in milling and cyaniding work can, with few exceptions, be itemized in the following manner:

1. *Salaries.* Superintendence.
2. *Wages.* Shift-men and laborers.
3. *General Stores.* Crusher and battery renewal parts, and battery sundries. Tube-mill pebbles and linings. Cyanide, lime, zinc, and general sundries.
4. *Repairs.* This expense is mainly dependent on the

The keeping of salary and wage accounts offers no difficulty and needs little comment, but it is important that time books should be augmented by other sheets showing the daily labor costs apportioned to each department and so arranged that the amounts can be easily totaled at the end of the period. I find it preferable, in the first instance, to enter amounts of wages due rather than shifts and fractions performed, and each entry is best accompanied by a notation indicating the particular department

class of machine erected, and is often inversely proportional to the original outlay. 'Repairs' should be kept separate from 'renewals', being generally beyond working control, although they cannot be excluded from working costs.

5. Proportions of power, lighting, and assay costs.

It is presumed that the plant is under the control of a works manager, generally termed a 'mill and cyanide superintendent'. The separation of management into two departments, when there is no line of demarcation in the treatment, makes the proper control of working costs an impossibility, and is a system which invariably results in friction and loss of efficiency.

to which the amount should be charged. Such books are generally kept by the shift-men in the mill and cyanide plant. Form 1 is an example of a page from such a book. A wages segregation sheet should follow and should be arranged so that the notations against each department correspond to those used in the wages book. Form 2 will serve to illustrate the idea.

Store accounts of material in general and constant use should be based upon the same plan, and the contents of the store book should be itemized, as far as possible, to correspond with the wages segregation scheme. The amount of stores consumed during a period should always be based

upon an inventory of what remains; and since cost sheets are rarely compiled oftener than once a month, the labor involved is small, the idea of systematic storage is inculcated in those responsible, and discrepancies and writ-

ing-off at ordinary stock-taking time avoided. The following is an example of stores subdivision:

1. *Rock-breaking.* Wearing plates, toggles, shovels, etc.
2. *Milling.* Shoes, dies, liners, stems, guides, etc.; mercury, screening, blanketing, etc.
3. *Fine Grinding.* Pebbles, liners, etc.
4. *Settlement.* Lime, etc.
5. *Agitation.* Cyanide, lead acetate, etc.
6. *Filtering.* Filter cloth, acid, pump spares, etc.
7. *Precipitation and Smelting.* Zinc, filter cloth and paper, soda, borax, crucibles, coke, etc.
8. *Sundries.* Oil, grease, waste, packing, belting, and sundry spares.

An example of store-book entry is shown in Form 3.

ASSAY COSTS

These should be compiled in the same way as general costs, the assayer being responsible for the expenditure as well as the stock of material in hand. A separate assay stock book should be kept, but no segregation of wages is necessary. A summary of costs should be compiled monthly, as illustrated in Form 4. A statement of cost

per assay can be added if required, but the result is generally misleading since the cost is not uniform, a bullion assay, for example, costing less than a fire assay. The total cost should be apportioned at the discretion of the assayer and reported on a sheet based on Form 5.

Consignments of assay office reagents and glassware should be entered in the store book on their arrival, and the cost totaled. A proportion of the amount, calculated to allow the expense to be spread over the period intervening before the next order, should be charged to 'chemicals and glassware' every month. The yearly stock-taking and calculation of value of a quantity of miscellaneous glassware and deteriorated chemicals is an absurd waste of time. Assay-office 'plant' should include balances, furnaces, and all apparatus, but not perishable articles.

FORM 7.

General expenses should not be included in a statement of working costs. The latter are purely for local use as a means of isolating and checking unnecessary outlay and for the encouragement of the introduction of economies.

A common mistake at the commencement of milling operations is to charge to capital expenditure or construction the complete sets of wearing parts erected with the mill. The error of the proceeding is perhaps more obvious in the case of the ball-mill where a set of liners delivered at the mine often costs as much as \$1000. To charge this amount to construction would result in a subnormal run-

ning expenditure for six months or so, and a considerable rise in milling cost when a new set of liners was necessary. These fluctuations would be awkward to explain to the millman; and such occurrences are often the cause of statements of working costs being withheld from those who are in the best position to effect economies. The cost of all wearing parts, whether shipped with the original machinery or not, should be separated from the total; and capital expenditure differentiated from what would subsequently be working cost outlay. This argument applies to rock-breaker spare parts, the wearing parts of any type of milling or grinding machine, and the original cloths or bags sent with vacuum-filters or filter-presses. The probable life of these can always be estimated with fair accuracy until actual data is available. In any case, a faulty approximation is preferable to a faulty system, and less difficult to rectify in the event of error.

Continental Type of Glacial Deposits in Alaska

By LAWRENCE MARTIN

*The glaciation of the interior of Alaska forms a striking contrast with the coast, where glacial erosion forms predominate, the deposits being largely under water, except for (1) 1600 square miles east of Yakutat bay, (2) 16,000 square miles in the Cook Inlet-Susitna Valley region, and smaller areas. The interior, between the coast ranges and the Endicott-Rocky Mountain system, where the National Geographic Society's party made some studies in 1911, has extensive glacial deposits of the continental type, previously described in part by I. C. Russell, A. H. Brooks, and others and similar to those of the United States. These include at least (a) 15,000 square miles in the Copper River basin, (b) 27,000 square miles in the Tanana and Kuskokwim valleys, (c) 17,000 square miles in the Yukon flats, (d) several thousand square miles on the upper Yukon region in Canada, and smaller areas. The dominant material is outwash, and this extends long distances outside the country actually glaciated. In places, there is wind-blown loess associated with this. In some localities it is still being deposited, and in the Copper River basin it has been accumulating during the time required for the growth of six or seven generations of trees. There is also some till, but this is largely buried beneath outwash. Lake deposits, eskers, kames, and buried vegetation are also found, but thus far no one has found drumlins. In thickness, some of these deposits rival those of the Middle West, one instance being known of probably 800 ft. of gravel and sand grading out from the mountains to less than 100 ft. fifty miles away. The presence or absence of these drift deposits seems to be chiefly a matter of favorable topography and existing deglaciation, a process much like that formerly in progress throughout the northeastern and central United States.

Filtration With Alundum Plates

Filtration of large volumes of liquids containing very fine precipitates, by means of asbestos fibre and the Witte plate, has been found very inconvenient at times. As substitutes for filter plates and asbestos, disks made of 'alundum' (fused aluminum oxide) have shown great efficiency. An ordinary flat rubber band stretched around the filter disk or plate makes it fit snugly to the funnel, when suction is applied by means of the filter pump. These plates may be had in several grades with pores of different sizes, those with the smallest pores retaining the finest precipitates perfectly. Their use saves the trouble of preparing asbestos and also makes it possible to stir the precipitates without danger of dislodging the filtering material as when asbestos is used.—*Jour. Amer. Chem. Society.*

*Abstract of paper read before the Geological Society of America.

Tube-Mill Practice and Liners

By F. C. BROWN

It is well known that the tube-mill came into the mining industry from the cement industry, and in adapting the machine for the wet-grinding of ores very little change was made in it, considering the very different class of work it was called upon to perform. In cement work the mills are usually of large diameter and the thick siliceous lining does not take up an unreasonably large percentage of the working area. This type of lining has a very long life in dry grinding, and the danger of siliceous blocks working loose is not great.

In wet grinding the conditions under which tube-mills are operated vary tremendously, and the mills and their method of operation require modification accordingly. In some cases the feed is very coarse, and medium or very fine grinding is required, while in other cases the feed is already very fine and the tube-mill is required to produce slime. Some mills are operated with a large quantity of material passing through them, the coarse, or not sufficiently ground particles, being continuously returned to the feed for further grinding; while other mills have a small feed and the material only passes through the mill. One would naturally infer that, in order to meet such a variety of conditions, the following factors in tube-mill practice would have to be carefully considered:

- Diameter of the mill.
- Length of the mill.
- Speed of the mill.
- Size of the pebbles.
- Load of pebbles.
- Percentage of moisture in material being ground.
- Lining of the mill.

a. Diameter of the Mill.—I have made careful tests with regard to this, and have come to the conclusion that it is a waste of power to use mills of large diameter when the material to be ground is already fine; my idea being that a mill of small diameter and small pebbles are the most economical for such work. For grinding the pulp coming from stamps crushing through wire screens having, say, six holes per linear inch, I have found mills of 4 ft. diameter inside the liners suitable. When finer crushing is done by the stamps, smaller diameter mills would answer as far as economy in grinding is concerned, but such small mills are inconvenient when it comes to relining and repairs. If it is a question of grinding a very coarse feed, say particles up to $\frac{1}{2}$ -in. diameter, I prefer a fairly large diameter mill, but even for this work a diameter of 5 ft. inside the liners is large enough, provided there is a suitable arrangement for returning coarse particles to the mill for further grinding.

b. Length of the Mill.—For grinding 6-mesh pulp from stamps so that it will pass 200 mesh, mills of 4 ft. diameter and 16 ft. long answer well. At the Broken Hill Proprietary mine of New South Wales, mills 4 by 13 ft. are doing good work in re-grinding tailing that will pass 10 mesh and leave 60% on 40 mesh; the finished product being of a fineness of about 10% on 40 mesh. One of the main objects in this case is to produce a minimum quantity of slime, and it is quite likely that mills of less than 13 ft. in length would do even better work.

Speaking generally, the length of the mill should be determined by the nature of the finished product required. If the object is to slime everything, the mills should be long, but if a granular or sandy product is required, they should be short; and in all cases they should be operated in conjunction with some efficient system of returning insufficiently ground particles to the feed. Two mills run in tandem with a classifying device between them will do better work than one mill of the same diameter with a length equal to the combined lengths of the two mills.

c. Speed of the Mill.—This is one of the most important factors in operating tube-mills, and depends upon the diameter of the mill and the type of lining used. With thick

lining like silex blocks it cannot possibly be correct during the whole life of the lining, as, in a 4-ft. diam. mill, these blocks when new take up 16 to 20% of the cubic content of the mill, according to their thickness. The usual speed for a mill 4 ft. in diam., lined with a smooth liner such as silex blocks or metal plates, is 32 r.p.m., and for a 5-ft. mill, 27 r.p.m. If these mills are lined with metal plates it means taking off 2 in. from the diameter to arrive at the working diameter, which would be 3 ft. 10 in. and 4 ft. 10 in., respectively, giving peripheral speeds of 382 and 407 ft. per minute. With silex liners these speeds would be considerably less, depending on how much the liners are worn. In an article by H. Standish Ball, 'Economics of Tube-Milling,' (*Mining and Scientific Press*, September 23, 1911), the most efficient peripheral speed for a mill 2 ft. 10 in. diam. inside the liners is given at 333 ft. per min (37 r.p.m.), and in the same article he gives the speed of the standard tube-mill used in the Transvaal, which is 5 ft. 6 in. diam. inside the shell, at 31 to 32 r.p.m. Such a mill lined with silex blocks would have a working diameter of 4 ft. 6 in. when the liners are new, and 5 ft. when they are worn and ready to be replaced, giving peripheral speeds of 445 ft. and 491 ft., respectively. In my opinion, this mill is running at too high a speed and the variation of speed due to the wear of the liners shows the unsuitability of silex blocks as liners.

d. Size of the Pebbles.—This should bear some ratio to the diameter of the mill and the kind of grinding to be performed. A mill that has been in operation for some time contains a good percentage of small pebbles, so the pebbles being fed to the mill can be larger than would be correct for a full charge. Pebbles ranging from 2 to 3 in. diam. answer for the usual grinding of pulp coming from stamps. For grinding coarse material, pebbles up to 5 in. diam. are suitable.

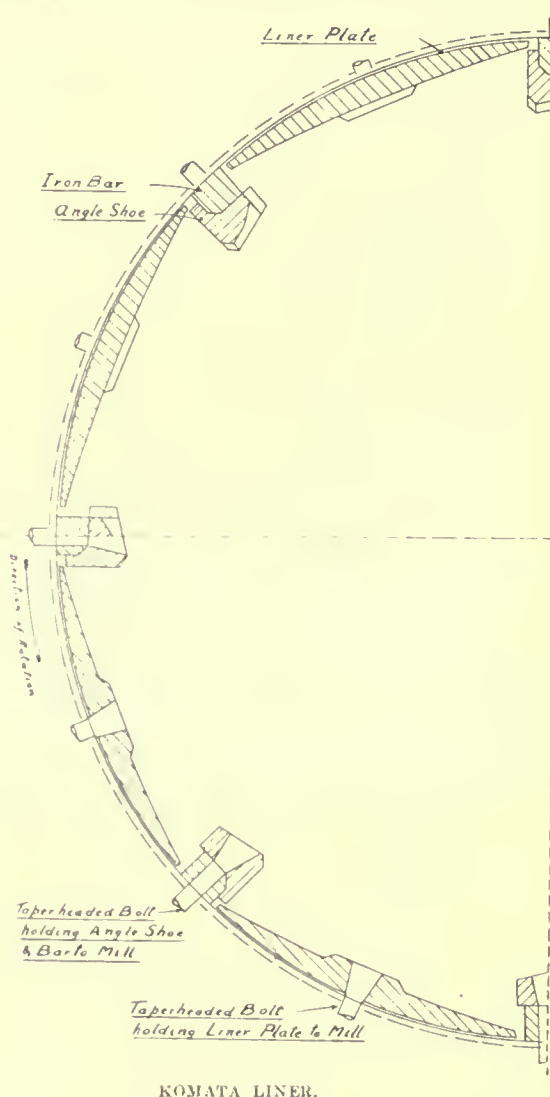

e. Load of Pebbles.—There is a great variety of opinion regarding this, but the usual practice is to keep it about up to the axis of rotation when smooth liners are used, although it appears that in the Transvaal the pebble-load for a mill 5 ft. 6 in. diam. is kept at 3 in. above the axis of rotation, according to Ball.

f. Percentage of Moisture.—This is a factor that is influenced by so many conditions that each mine has to find out by experiment what answers best. The percentage of moisture should range from about 38 to 50%, and depends on the specific gravity, coarseness, and nature of the material to be ground. The percentage of moisture has a very marked influence on the grinding, and the eliminating of slime from the feed is also of great importance.

g. Lining of the Mill.—The first mills used for ore were lined with either silex blocks or smooth metal plates, both of which fall far short of being an ideal lining, as the former takes up too much space in the mill, and the latter allows the pebbles too much back slip. The improved liners are the Honeycomb, the El Oro, and the various forms of corrugated metal liners, all of which have their distinctive feature of merit, and I have recently introduced in this country a ribbed liner known as the 'Komata' liner (named from the Komata Reefs mine of New Zealand, where it was first used). This liner is now used by most of the mines in New Zealand and has been adopted by the Goldfield Consolidated Mines Co. of Nevada, the Tonopah Extension Mining Co. of Tonopah, and the Associated Milling Co. of Manhattan, Nevada. It has the very important feature of only slightly altering as regards thickness and shape during its whole life, is easily and quickly put in place, has a remarkably long life, and shows a greater grinding efficiency and decreased consumption of pebbles compared with other liners. The nature of this liner is shown by the accompanying sketch. Its adoption requires an alteration in the speed of the mill and also in the load of pebbles. The former should be about 330 ft. per min., peripheral speed, for mills of 4 to 5 ft. diam., and the latter should be 5 to 7 in. below the axis of rotation, depending on the diameter of the mill. These figures are deduced from New Zealand experience, and it will be interesting to see what the results are from tests made in

this country. The Edgar Allen American Manganese Steel Co. has the manufacturing and selling rights for the Komata liner.

There are several theories regarding the exact action of the pebbles in a tube-mill which produces the grinding of the sand or ore, some claiming direct impact or impingement as being the most important factor, while others lay stress upon the rubbing or abrasive action. In my opinion, it is difficult to come to any exact conclusion, but viewing the matter from a strictly practical standpoint, I lay the greatest stress upon the movement of the pebbles, my experience being the more movement the more grinding; hence

the advantage of the Komata liner, as this permits of no 'dead' place in the mass of pebbles and ore.

Direct impact is certainly not the only factor in grinding, as I have fed 1/3-in. diam. particles of hard quartz to a 4-ft. diam. mill and they were discharged slightly rounded after the first passage through the mill, but being several times returned, they gradually become converted into slime, and no doubt very fine slime, just what is required with some ores for high extraction. This might be an explanation of the fact that the addition of tube-mills to a plant, even if the ultimate fineness of the grinding, ascertained by sieve tests, is about the same as before the tube-mills were used, often shows a remarkable increase in extraction. It has always seemed good practice, from my experience, to have a certain amount of very coarse sand continuously going to a tube-mill along with the feed, as this materially increases the grinding efficiency.

DANISH pebbles were exclusively used when tube-mills were introduced in America. In fact, the pebbles came from Iceland, being merely distributed from Copenhagen. Now pebbles from many localities are available, and hard ore is commonly used for grinding.

Alamos District, Sonora, Mexico

By G. L. SHELDON

This district is situated in the most southerly part of the State of Sonora, and is reached by a branch railroad from the main Southern Pacific line at Navajoa. Ramon Carral, the former vice-president, was a native of Alamos, and when the concession was given to the Southern Pacific company he insisted that the main line or a branch must be built to Alamos. The surveyors found that they could not get a 1% grade through Alamos, and the branch was therefore built. The altitude of the town is 1300 ft. It is in the foothills on the east side at the base of Alamos mountain, which is 5100 ft. high. This insures a good climate, the best, in fact, enjoyed by any town on the West Coast. The population is 12,000 to 14,000. Alamos is a rather pretty town, clean and with a water system. There is considerable wealth. It is the main supply point for a large agricultural and mining territory. The town is a little over 100 years old. About forty years ago the lower portions next to a creek, which is generally dry and heads six or seven miles above, was swept clean by a winter flood, only leaving the few large *alamos* (poplar) trees, 4 to 6 ft. in diameter that mark the place.

The district contains many mines. West of the town about five miles, on the north side of Alamos mountain, which stands practically alone, are several silver mines. The old Promontorio has been worked, practically continuously, for over 200 years. A *higuera* (wild fig) tree, 2½ ft. diam., can be seen growing in the old mine dumps. These dumps are immense and contain easily one-half million tons. They are sufficiently valuable to warrant re-treatment. It is claimed that the mine has produced 100 millions, but this is probably exaggerated. An English company purchased and worked it for many years, finally selling it to Clemente Ibarra for \$14,000; one-half being in goods in the company store, taken at wholesale price some fifteen years ago. Sr. Ibarra tells me, and this is confirmed by his bankers who handled the bullion, that he took out more than \$500,000 from the old works without doing a foot of new work. The mine is 800 ft. deep and makes considerable water, which, however, is needed for milling. There are three veins, each 30 to 40 ft. wide, in a width of 200 ft. In depth copper is found. Six or seven years ago Ibarra sold the mine to Texas people for \$100,000. About three years ago they in turn bonded it with a cash payment, to Los Angeles men, for \$100,000. This appears to have been more of a stock promotion than a legitimate mining enterprise, and the property reverted to the Texas owners.

Adjoining the Promontorio, on the north, is the Quintera. Some forty or fifty years ago a Frenchman owned it and the Rosario, a lead-silver property on Rosario mountain where the States of Sonora, Sinaloa, and Chihuahua touch. He had worked the Rosario extensively, the ore being a lead carbonate containing much silver. He finally went to Paris and mortgaged both properties to the Egyptian-Paris Bank for \$250,000 and skipped out to South America. He has never been heard from since. After the bank acquired the properties, for many years they sent out each year engineers to examine and report on the property. Finally, about thirty years ago, after several had reported favorably upon the Quintera, work was commenced. The vein is strong on the surface, 18 to 20 ft. wide, and has granite on the east and a dark andesite on the west. It showed low silver values on the surface and 2 to 3% lead. With depth the value of the ore improved, and, under the efficient mine management of Tom Clark, a Cornishman, the mine for years paid \$50,000 to \$100,000 in dividends, notwithstanding that the general mill management was expensive. The mine is on a hill 700 ft. above the mill. An aerial tram was put in to bring the ore to the mill and a shaft 500 ft. deep sunk at the north end of the property. From this a drift was driven 1300 ft. south, and a winze sunk, ultimately 1000 ft. All of the ore was thus hoisted twice and trammed 1300 ft., when an adit from the mill

2000 to 2500 ft. long would have tapped the winze 200 ft. below the long drift, and the ore could have been trammed in cars direct to the mill. Even when a new shaft was sunk from the surface, this was done near the old one, instead of raising from the winze on the 500-ft. level. The vein at depth, for 20 to 30 ft. in width, would assay 40 to 50 oz. in silver. Lead gave out and copper came in to the amount of 8 to 9%. The copper ore was sorted out and smelted on the ground, using mesquit charcoal at a cost of ½¢. per pound. At the 1500-ft. level the vein split. One branch was followed to the east in the granite. It contains no ore of value, and the mine has been idle for years. A few hundred feet north of the shaft the vein enters the granite on both sides and becomes barren. At the south end of the property the ore-shoot appears to be dipping into the Promontorio.

About 3000 ft. north of the Quintera is the old San Domingo mine, with a record of two or three million pesos production. It is 250 ft. deep. This had been idle for many years. Eight or nine years ago Chicago men purchased it for \$5000. Under the management of J. R. Hendra, a nephew of Tom Clark, it has been well developed and a mill has been erected. This ran last year until the political disturbances shut things down. A good grade of concentrate containing silver, lead, and gold was made. Cement pillars were found in the old mine. The San Domingo is entirely in andesite, which extends for 1000 ft. south. North of the San Domingo for 1½ miles, the vein is also in andesite. There it has been worked little and to no great depth. At the north end is the Minas Nuevos, better known as the Zamboni. It is entirely in the andesite. This was purchased several years ago from Zamboni by California men. A complete up-to-date plant with Pachuca tanks is in operation. The company is treating old tailing together with ore from the mine. The latter is about 400 ft. deep. The vein is 20 to 30 ft. wide and contains on an average 24 oz. silver, with some lead and lime. The latter makes it difficult to obtain good results with cyanide. Gold bonds have been placed upon the property, to the extent of \$250,000, for its development and for building the plant. The mill and mine are within a few hundred yards of the railroad with a switch to it. North of this the vein runs into the granite, and is barren.

Three miles south, at Minetas, on the same 'mother lode', is an old mine idle for many years. Within the last three years several discoveries and many locations have been made to the north, connecting the work with Bacanri. The La Junta mine, a recent discovery on the flat, is owned by a dozen Mexicans, and during the first six months shipped \$65,000 worth of ore. It is developed to a depth of 100 ft. At this level one breast, sampled by people who had an option, was found to assay \$700 per ton. When, however, the men having the option had made up their minds to take the property and presented a certified check for \$20,000 as first payment, the owners refused to accept it, the option having expired at midnight previous, and doubled the price. No one has been able to buy the mine and the owners divide the ore on the dump. Recently C. W. Smith, who has a 10-stamp mill within a few hundred yards, has been milling second-class ore on shares; with very satisfactory results. Mr. Smith, representing Chicago men, is developing a 75-ft. vein by shafts and hoists. The vein is somewhat split up in this vicinity.

Two miles north, McCarthy and Wilson are developing a promising prospect at 200 ft. in depth. They have 12 ft. of 1-oz. gold ore and have made arrangements to put on a mill. Near them is a prospect that sampled on the surface only \$2, but which at 20 ft. in depth shows \$10 ore. It appears more than probable that a nice gold belt will be developed here.

Thirty-five miles north of Bacanri, on the Cedros river, is the town of Cedros. Two miles west is a large iron property, the ore being exposed in a small hill 250 to 300 ft. high, and the outcrop being several hundred feet wide. It can be traced for over three-fourths of a mile and shows heavy black oxide, high-grade, and said to contain \$4 in gold. Fifteen miles north of Alamos on the

main wagon-road is the Piedras Verdes copper property which has been examined by many engineers. It makes a great showing of oxides and carbonates on the surface. Soon after location twelve years ago several tons of high-grade boulders of copper oxide was picked up from the surface and shipped. The vein can be traced for several miles and some 1200 *pertenencias* were located upon it. The Mexican owners went half a mile east of the main best surface showing and sank a shaft 347 ft. deep. Off from the vein several hundred feet north a shaft 250 ft. deep was also sunk on the best showing. They did a good deal of gophering on the high-grade oxide streaks underground. Later some Boston people drove an adit in on the west part, finding a body of iron pyrite. Three years ago Seeley W. Mudd drilled several holes on the property, but did not take up his option.

Two miles further north is the Copper Queen. It is in the schist with a conglomerate and porphyry nearby. The deposit is 90 ft. wide and about 500 ft. long. Some high-grade ore has been shipped from the surface, but no development to any depth has been undertaken. The property was examined eight years ago by a prominent mining engineer and strongly recommended, but satisfactory terms could not be made with the owner. A few miles east of this

put in it. On the south side, however, a shaft has been sunk 100 ft. in the porphyry on a 4 to 6 ft. vein, probably only an offshoot from the main deposit. This shows good ore with 6 to 20% of copper sulphide. A long cross-cut run 350 ft. below on the south side has never reached the vein or deposit. The company ran out of funds and quit before this was completed.

Ten to twelve miles still further east of this place, at Piechi Cuata and Sabina Cuata (the latter named from two *sabina* or *savin* trees which at 40 ft. in height unite) is a small gold district, that extends over into Sinaloa. The Arcadia gold mine, after producing \$12,000, was sold to Denver people for \$20,000. They put up a 10-stamp mill, but never developed the ore-shoot from which the former owner took ore. The mill has been idle several years. At Sabina Cuata during the past fifteen years some desultory work has been done on several prospects but not sufficient to determine their value. This side of Piechi Cuata is the Babahuahua creek which, for twenty miles including its left-hand fork, carries placer gold. I had a zone on the upper portion of it prospected fourteen years ago, but would not locate it, since at that time there had been several hundred thousand dollars spent on the creek without result. Expensive machinery had been brought in and long

CHURCH BUILT IN 1531 AT QUEIRAGO, ALAMOS DISTRICT.

is a group of other copper prospects in the porphyry. Nine miles north of Minas Nuevos and within three or four miles of the railroad station Victoria is an iron property in the limestone. The Quintera company obtained iron for flux from this. It contained sufficient silver to pay the cost of working. There are places in the deposit showing considerable copper, but the iron is dense and heavy.

Northeast of Alamos, sixty miles on the road to Chihuahua, not far from San Bernardino and near the State line of Chihuahua, has been discovered during the past year and a half, a large low-grade gold and silver prospect. One hundred claims have been located upon it, extending for several hundred feet in width. It is claimed to contain \$5 to \$7. About twenty miles east of Alamos, near Plomitas, are several old lead-silver mines in which a little development has been done in recent years. Ten miles farther east is the El Cobre mine, worked by Frederic Erbe twenty to thirty years ago. He put up a small furnace and shipped considerable matte. The vein is entirely in the porphyry. During recent years some work has been done to a depth of 150 ft., at which depth a stringer from the main vein showing copper sulphides was cut. Six to seven miles southeast is the Copper Iron King property with a large hematite gossan impregnated with copper. This contains small amounts of gold and silver. The property is practically undeveloped and apparently lies in porphyry, but it has the marks of a copper mine. At about the same distance southwest, at La Mina, is another copper prospect which makes a good surface showing. A small limestone mountain 500 ft. high and about the same distance in diameter is covered with a burnt, honey-combed iron gossan containing a little copper carbonate. Not a shot has been

FREIGHT TRAINS ON THE CHIAPAS ROAD, NORTH OF ALAMOS.

bedrock ditches run. One Belgian company, after spending \$30,000 for machinery, sent a California placer expert to examine the property, and after receiving his report they quit. A Kansas City company put in a centrifugal pump and cleaned up bedrock in several places, obtaining \$1200 worth of gold at a cost of \$28,000. A Cripple Creek company sold stock all over the United States and in the City of Mexico and did some ditch work in order to clean bedrock. They never made a dollar except from the sale of stock. There is a little gold everywhere. The natives have worked it for hundreds of years. What is left is only what they could not get on account of water. The grade of the creek is too light for sluicing or hydraulicking. As to dredging, the bedrock is a rough ragged diorite, with many large boulders. It is doubtful if any profit can be made here. So far the source of the gold has not been recognized. The country rock is granite, quartzite, diorite, and andesite. A few small gash veins in the granite have been found.

There are numerous copper veins in Alamos district, mostly in the porphyry. These generally show good surface value, and some small lots have been shipped and others sold to the Quintera company. None have been sufficiently developed to determine their permanence, or their value in the sulphide zone. There are a few iron gossan deposits that ought to make copper mines. It is certain if they were in Arizona the showing would be sufficient and they would have been proved long before this. There are many other prospects in the district, some that I have seen, many others which I have not. This is only an outline. Practically all of the production of the district has come from the 'mother' vein. There is a nitrate of soda deposit which possibly with development may prove of commercial value.

Alunite Near Marysvale, Utah

By B. S. BUTLER and HOYT S. GALE

*An important deposit of alunite, which has but recently been discovered in Utah, is now being developed with so favorable a showing that it promises to afford one source of the much desired class of materials commonly referred to as potash. Although a large vein of 'pink spar' in the hills southwest of Marysvale had long been known to prospectors and had been repeatedly located for small metal content said to exist in the silicious wall rock of the vein, it was not until 1910 that the true nature of the spar was discovered. Specimens sent to the United States Assay Office at Salt Lake City in November 1910 were later forwarded to an Eastern chemist, who is said to have recognized the real value of the material. On January 1, 1911, the claims that had been allowed to lapse were relocated for the sake of the newly recognized deposit.

THE DEPOSIT AS A SOURCE OF POTASH

Alunite has long been used abroad as a source of potash alum, which it resembles in chemical composition. The alunite contains a relatively larger proportion of alumina than the common potash alum. It is insoluble, but is readily converted to either the soluble potash alum or potassium sulphate by a comparatively simple process of heating, or calcination. A process that has long been established commercially may doubtless be adapted to the American deposits. The Marysvale deposit, so far as now known, is not of such magnitude as to afford a source of all the potash salts now consumed in the United States, but it may prove to be an important factor in providing an American supply that will perhaps be especially available to local and Western markets, particularly in meeting the demand for higher-grade salts. Possibly also the greatest importance of the commercial development of this deposit will be in the added stimulus it may afford to exploration for other similar deposits of this mineral, especially in this general region, and it is on the discovery of such other deposits that the provision of a home supply from this source must depend.

The newly discovered deposit of alunite is situated near the head of Little Cottonwood canyon, about 7 miles due southwest of Marysvale, Piute county, Utah. It is situated in and near Sec. 16, T. 28 S., R. 4 W., and so far as known is covered by mining-claim locations. Marysvale is the present terminus of the San Pete & Sevier branch of the Denver & Rio Grande railroad. The deposit lies high in the Tushar range, outcropping near the top of the ridge separating North Fork of Little Cottonwood creek from the main branches of Little Cottonwood canyon. The vein and silicious wall rocks form the crest of the high ridge leading up to the main divide. The deposit ranges in elevation from approximately 11,000 ft. above sea-level to about 9900 ft. at its present recognized lower end, which is about 4000 ft. above the railroad at the Marysvale station.

CHARACTER OF THE VEIN

The alunite of the Marysvale deposit lies principally in a large banded vein, cutting at steep inclination the volcanic rock (dacite or andesite) which forms the greater part of the Tushar range. The large vein is evidently a fissure filling and not a replacement of the country rock, as the main body of the deposit is remarkably pure, and has the banded or crusted structure of a typical fissure vein. That replacement has not produced the larger bodies of alunite is further attested by the fact that the main vein contains but little silica, while in the wall rock where replacement has occurred the quartz phenocrysts remain practically unaltered, and silica that has been set free from the decomposition of other minerals has not been removed.

CHARACTER OF THE ALUNITE

The larger bodies of the Marysvale alunite are of unusual size and notably free from foreign material. The

mineral occurs in massive form, being in part a fine-grained compact rock, breaking with conchoidal fracture, and having a porcelain-like appearance, but containing also considerable masses with a distinctly crystalline structure. A considerable part of the vein material at the outcrop, however, is more or less of an amorphous texture and commonly sheared to a foliated or schistose structure. The crystalline material is generally clear pink to reddish in color, and the finer-grained rock varies from a white to a decided pink. The fine porcelain-like material, in which analysis shows the presence of 9.7% K_2O , is seen under the microscope to be a granular mass composed of irregular crystals of alunite. Through this fine-grained material are scattered small veinlets of more coarsely crystalline alunite. The coarsely crystalline portion of the deposit, which contains 10.46% K_2O , shows the more distinct crusted structure. The crystals are subtransparent, show a distinct cleavage, and are of a rather coarse granular or tabular form, yielding a splintery fracture in the mass of the rock. The elongation of the crystals, though showing a tendency toward radiation in tufts, is, however, roughly parallel and is normal to the vein banding and the walls.

EXTENT OF THE MARYSVALE DEPOSIT

The principal claims located on the Marysvale alunite deposit are the Custer group, shown by the accompanying figure. The group of claims adjoins patented mineral ground and recorded claims both to the northwest and southeast, as is indicated on the map. The Custer group covers the greater part of the alunite deposit as now recognized, the first location made expressly for the alunite having been staked January 1, 1911. Property to the northwest of the Custer claims is said to be covered by mineral locations under the control of the Florence Mining & Milling Co., lessee of the Utah Gold Mountain Mining Co., including the so-called Log Cabin property and also the patented ground known as the Bradburn property. Southeast of the Custer claims is the patented ground of the Clyde property.

A conservative estimate of the tonnage in this deposit may be had by assuming an average width of 10 ft. in the principal vein for a total length of 3500 ft., and neglecting the rest of the deposit as not sufficiently proved to be taken into consideration at present. If the recoverable potash or potash (as K_2O) is estimated at 10% of this total, such a deposit would yield 30,000 tons of potash for each 100 ft. in depth. This is approximately one-sixth to one-seventh of the total annual consumption of potash in the United States.

SUGGESTIONS AS TO PROSPECTING FOR ALUNITE

Until recently there has been no incentive to search for alunite, and most of the known occurrences in this country have been noted by geologists who were making studies of the areas where it occurs. There is little doubt that if prospectors had searched for alunite with the same diligence that they have shown in their search for the metallic ores, a far greater number of occurrences would be known. Since it was shown by F. L. Ransome that alunite is associated with the rich gold ores of Goldfield, Nevada, it has attracted more attention, and if the mineral itself proves to be of commercial value the search for it will be still further stimulated.

In the case of a mineral whose occurrence has been studied in so few places, it is impossible to give a definite and positive statement of the conditions under which it may be expected to be found; or if such a statement were made it would probably be modified by future discoveries. The study of the occurrences thus far described, however, does point rather definitely to certain conditions under which the mineral may form, and the conclusions derived from this study may therefore aid in a further search for it. There are at least two distinct conditions under which the mineral is deposited:

1. It may be formed by the action of descending acid solutions, derived from the oxidation of sulphides, on potassium-aluminum silicates (feldspars or micas). Several occurrences have been noted where the mineral is thus asso-

*From Bull. 511, U. S. Geol. Survey.

ciated with oxidized ores, usually in or close to feldspathic rocks, and a more careful examination of material that has been called kaolin and talc will doubtless show some of it to be alunite. As yet no body of this type that promises to be of commercial importance has been discovered, but it is by no means impossible that such bodies exist, and large bodies now described as kaolin and talc, but not definitely known to be such, may well be tested to determine whether they are not alunite. It may be stated in this connection also that the closely allied mineral jarosite has been noted in the oxidized zone of several orebodies, and this mineral, too, may in some places occur in considerable abundance.

2. The deposits that at present give the greatest promise

As has been pointed out, it is believed that the Marysvale deposit is closely associated with metallic veins of a type widely distributed through the Western states. It is certain that in some of the districts where such veins occur alunite is not present, at least not in important amounts, but it is by no means improbable that it may be found in other districts, and an examination of supposed 'spar', 'talc', or 'kaolin' veins may show the presence of the mineral. Although it may be expected to occur in districts with metal veins and is believed to be closely related to them in origin, the alunite deposits themselves may not contain important metal values, as is indicated by the Marysvale deposit and the two Colorado deposits that are known. On the other hand, as at Goldfield, it may be closely associated with the metallic deposits. In the Tushar and neighboring ranges there are reported to be numerous silicified vein outcrops described as 'geysers', which on examination may prove to carry alunite or other salts of commercial importance.

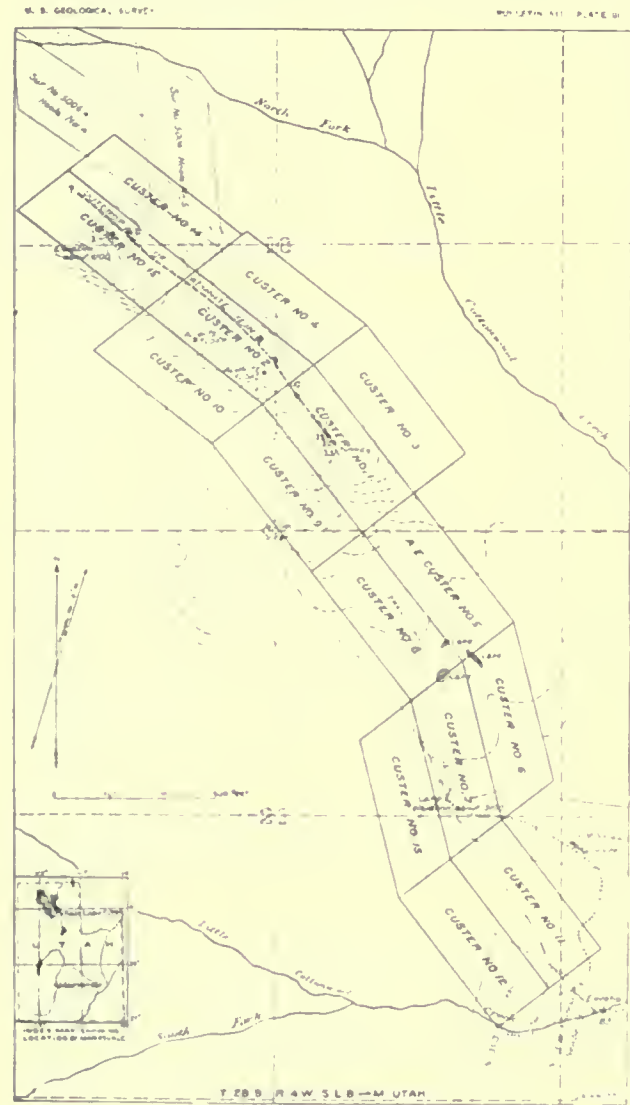

FIELD TEST FOR ALUNITE

The following field test for the mineral alunite has been suggested by W. T. Schaller: Boil the powdered sample with water or with hydrochloric acid for several minutes; after allowing the powder to settle, pour off the liquid and repeat the operation to insure the removal of all soluble sulphates. Dry the powder and heat to a dull red. Again boil in water and, after settling, pour off some of the clear liquid. To this add a small fragment or a solution of barium chloride. If the mineral is alunite a heavy white precipitate will form. To be sure that the water used in this test does not contain sulphates in solution, it should be tested with barium chloride, and if it gives a marked precipitate it cannot be used. For this test, all that is required that is not included in a miner's or prospector's outfit is a little barium chloride, which can be carried in a small bottle or cartridge.

WARNING TO INVESTORS

Deposits may exist on ground adjoining the claims already located and partly developed, but it should be borne in mind that the present developments have not yet proved the continuity either in depth or even with certainty for a very great distance on the surface. Prospective investors should understand that until the true character and commercial availability of a deposit of this type has been demonstrated, they are taking chances in investing in the stock of any company professing to be about to develop such a deposit. The Geological Survey has been assured on reliable authority that the property covering the best-known part of the alunite deposit which is described in the foregoing pages is not for sale, and its owners are not in need of assistance, financial, technical, or otherwise, for the development of the property to its best advantage. It should be unnecessary to say to anyone who is familiar with the usual procedure in such an enterprise that if responsible persons have secured control of a deposit which offers large and unusual promise but whose actual commercial value is not wholly proved, it will not be necessary for them to advertise widely for contributions or express a willingness to distribute large quantities of stock, if they actually intend to develop the property on a commercial basis. Such a procedure should of itself be a warning to any who may be contemplating an investment of this character.

Growth of the copper industry in the United States has been notable, according to the figures of the United States Geological Survey. In 1850 the production was 1,456,000 lb.; in 1890 it was 259,763,092 lb.; in 1900 it had increased to 606,117,166 lb.; in 1905 it was 901,907,843 lb.; and in 1909 it had passed the billion mark with 1,092,951,624 lb., decreasing in 1910, however, to 1,080,159,509 lb. The price has decreased from over 46c. per pound in Civil War times to an average of 12.7c. per pound in 1910. The United States is by far the largest copper producer in the world; in fact, it produces more than all the rest of the world together.

PRINCIPAL GROUP OF CLAIMS, MARYSVALE, UTAH.

of commercial importance have resulted either from the action of hot waters carrying sulphuric acid on rocks containing potassium-aluminum silicates or from the deposition in veins from ascending thermal solutions. In the former type the resulting alunite is largely disseminated through the altered rock, though small veins of nearly pure material are not uncommon; in the latter type, as shown in the Marysvale deposit, it has been carried in the solutions and deposited as a large vein. The deposits of these types thus far discovered have been in or closely associated with the extensive bodies of Tertiary igneous rocks that are abundant in the Great Basin and Rocky Mountain region. In connection with the alteration that has produced the alunite, there has been a silicification of the rock which has rendered it resistant to weathering, and the outcrops are usually rugged, standing above the surrounding rocks. Pyrite is also commonly formed in the wall rock during the alteration, and in places the oxidation of this mineral at the surface imparts an iron stain to the outcrop.

Labor Conditions in Arizona Smelters

B. W. J. LAUCK

Only about three-tenths of the employees in smelters in Arizona are native Americans. Six out of every ten are Mexicans. The remaining one-tenth is composed of immigrant workmen from Great Britain and northern Europe, the English, Irish, and Scotch being represented in largest numbers. Such is the racial classification of employees of smelters in Arizona disclosed by the recent investigations of the United States Immigration Commission.

Almost one-half of the Mexicans employed in the Arizona smelters have been in the United States less than five years, and three-fourths have a residence in this country under ten years. The majority of the English, Irish, German, Scotch, and Swedish wage-earners, on the other hand, have been here ten years or over, and a considerable proportion for a longer period than ten years. Unlike the southern and eastern European employees in Colorado and other states, the foreign-born workers in the Arizona smelters, due to the preponderance of the Mexicans and the presence of the British and northern European immigrant, have, as a rule, their wives with them and maintain an independent form of family life. Practically all of the German and Swedish employees of foreign birth speak and read English. On the other hand, only 8% of the Mexicans speak English, and less than 5% read and write the language. In the same connection it may be stated that only 5 out of a total of 208 Mexican smelter workers for whom information was received by the Immigration Commission, had become citizens of the United States.

Of the native white American workers in the Arizona smelters about one-tenth were foremen, one-fourth were engineers or mechanics, and only about three-fifths were general laborers. Considerable numbers of the English-speaking immigrant employees were foremen or mechanics. One out of every ten Mexican employees who had been born in the United States were engineers or engaged in mechanical work. All of the foreign-born Mexicans as well as the native negroes were unskilled laborers. The hours of labor at the smelters ranged from 8 to 12 per day. The furnacemen, feeders, tappers, punchers, vanner and jigmen, and helpers worked 8 hours, as did the engineers, motormen, and firemen. Some mechanics worked 8 hours, some nine hours, and others 10. General laborers worked from 8 to 12 hours, but most commonly 8 or 9 hours.

Wages ranged from \$1.50 per day, the rate received by over 40% of the Mexicans, to more than \$8 per day, which was paid to a few of the foremen. General laborers were paid wages varying from the lower rate named to \$4.32 per day. Few, however, received more than \$3.50. Of the Mexicans employed as general laborers, 87% were paid less than \$2.50 per day; while of the foreign-born other than Mexicans in this occupation group, 85% received more than \$2.50 per day. The great majority of the general laborers of the native American and the north European races received from \$2.50 to \$3.50 per day. The differences in the wages paid the Mexicans and those paid native-born and north Europeans employed as general laborers are partly due to differences in the places held by individuals of these races as general laborers, but they are largely accounted for by discrimination against the Mexicans in the payment of wages. The wages paid engineers and mechanics ranged from \$2.55 per day paid car-repairers, to \$4.75 paid some of the engineers. Blacksmiths, as a rule, received \$3.50 per day; boiler-makers, \$3.75; carpenters, machinists, cranemen, and bricklayers, \$4; tinsmiths and iron-molders, \$4.25. Foreman received from \$2.75 per day paid to the foreman of the re-lining pit at one smelter, to more than \$8 per day paid the foreman of the concentrator at another.

THE grand total of excavation for the Panama Canal to January 1 was 158,092,940 cu. yd., leaving 37,230,439 cu. yd., one-fifth the entire amount for the completed canal.

Peruvian Mining News

Chucuitambo Gold Mines.—The cyanide plant for the mines of this company at La Quinua, Peru, was expected to be ready for operation by the middle of January. It is of 120 tons daily capacity, and it is believed that ore can be supplied at present up to 75% of this, as development has been going on steadily while the plant was being constructed, shipments having been reduced below the figures of a few months ago in consequence. The saving of 85% which is counted upon in place of the 66% previously made, together with the known richness of the ore, should make this a steady dividend payer.

Ferrobamba.—The whole of the resources of the Ferrobamba company are being concentrated on proving the property as quickly as possible. Prospecting work is being carried on more vigorously than ever, and some fifteen faces are being driven. At the present rate it should not be long before the owners can arrive at a determination as to the building of the railway to connect with the Southern, and in general as to the future operations to be conducted. This property has aroused more discussion than any developed in Peru since the Cerro de Pasco Mining Co. was organized.

Andaray-Posco.—The Sociedad Aurifera Andaray-Posco, Ltd., operating in the Province of Condesuyos, with a paid-up capital of £50,000, is now making very good progress under the able management of Robert P. F. Prain. In November the president of the company, Don Gil Galté, and another director visited the property and were pleased with its present condition. The 3-kilometre canal is practically finished, so also is the dam and intake. The new plant which lay in Chira for close on four years, is now at the mines, and erection work will be started as soon as the necessary timber arrives, which will be in about a month's time. Since January 1911 the probable ore reserves have been increased by about 5000 tons.

Cerro de Pasco.—The Cerro de Pasco M. Co. has now had in operation for some months its new 20-ft. long Pierce-Smith basic-lined converter, and the basic-lined ball-type converter designed by the late Charles F. Shelby while superintendent of the smelter. These two modern converters take the place and do the work of the battery of six acid-lined bessemer converters formerly in use, with marked economy. In the new types the lining remains good over several months of use, and when it is burned out it is readily renewed.

Moquegua is an old Spanish city in the heart of a rich olive and grape country, and the terminus of the Ilo-Moquegua railway recently acquired under a 25-year lease by the Peruvian Corporation. The city is situated among the coast hills about 100 kilometres from the port. A spur of the main range of the Andes rises abruptly from the low coast range some 10 kilometres east of Moquegua, whence very rough and mountainous country continues back into the interior. A considerable amount of Bolivian trade passes through this region, taking two months for the journey with llamas. Forty-five kilometres to the north-east of Moquegua lies the promising mineralized region of Sipineallani, where vein mines have been worked extensively by miners of the Spanish colonial period. Important deposits of pure native sulphur in this same region indicate great volcanic activity at some past time. A bed of volcanic tuffa at one time has covered the entire district, but exists today only on the hilltops. There appears to be an extensive low-grade copper deposit in sandstone, the value of which, however, is problematical, considering the topography of the country. Beautiful stalagmites and stalactites are found in caves, and the stream beds show the effect of much leaching. It is a field which justifies the prospector's attention.—*Peru Today.*

PRODUCTION of antimonial lead in the United States in 1910 was 14,069 short tons, valued at \$1,338,000, as against 12,896 short tons, valued at \$1,231,019 in 1900; and 13,629 short tons, valued at \$1,264,771, in 1908.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Central American Mines in 1911

The Editor:

Sir—In an article by T. Lane Carter on Nicaragua, in your issue of January 6, speaking of the dip of the vein, he says that the title to deep-level claims is uncertain, but that it is probable that the Government will change the law in this regard. Let me point out that the revised (Sept. 26, 1911) mining laws of Nicaragua were published in your issue of November 4, 1911, where the changes made relating to the dip are given.

SYDNEY ADLER.

New Orleans, January 15.

Costs at Arco, Idaho

The Editor:

Sir—The correspondence from Arco, Idaho, on page 116 of your issue of January 13 interests me. I cannot, however, make the figures check out, and as I have a prospect containing similar ore, I would be greatly obliged if you can enlighten me.

23% lead (at 4½¢ (N. Y. price).....\$20.70
With 2 oz. silver and 15c. gold..... 1.15

Gives gross value of ore, as stated, of....\$21.85
80% recovery equals \$17.31
The concentrate, running 50% lead and 5
to 6 oz. silver, figures a concentration of
about 3 into 1.
Cost of mining and milling 3 tons (at \$1.50).....\$ 4.50
Cost of freighting 1 ton (at \$3.25, plus 25c.
for moisture 3.50
Cost of smelting 1 ton..... 5.80

Total cost on 3 tons ore.....\$13.80
Or say \$14.89 as given, or say \$15.00, gives
cost per ton of ore..... 5.00

Leaving a profit per ton of ore of..... \$12.31

It is plain that \$21.85 gross value less \$14.89 total cost leaves \$6.96 as profit (your correspondent's figures), but this does not seem to solve the problem.

The pickings from the belt of the high-grade ore may account for the difference between my conclusion, \$12.31, and that of your correspondent, \$6.96 per ton; but, on the other hand, the average value of the ore is apparently the basis of his figures, as it is of mine. I am inclined to believe the \$6.96, as the lower figure, more nearly the correct net value of the ore, as the lead is figured rather high—though not too high, perhaps, seeing there is a smelting charge made for an ore that smelters will treat free of charge if an allowance is made on the price of the lead for getting it to the New York market.

GURDON BRADLEY.

Berkeley, California, January 19.

Precipitation of Copper From Mine Waters

The Editor:

Sir—The article, 'Precipitation of Copper from Mine Waters', contained in your issue of November 18, invites comment and correction—certainly here in Spain, the 'home' of the ancient process. Important matters are referred to in it in a didactic yet incorrect manner, and it is abundantly evident that the lapses have been occasioned through the ignorance of the writer of the article in question of certain well known and recorded facts of historical mining

science, both in America and in Europe. I say America advisedly, because those facts were current there in the seventeenth century. An equally public correction of such erroneous statements is certainly due to the public in the interests of technical journalism and of proper record; more particularly as they have appeared in such a valuable means of distributing information and of important scientific knowledge as the *Mining and Scientific Press*.

The second paragraph of the article under estimation has it: "Twenty-three years ago [1888] the making of copper through the employment of mine-water (sic) was unheard of, and it is difficult to say how much copper went to waste in the early days through failure to use this method. A Welshman named Morgan was the discoverer. In 1880 while living near the gulch through which ran the waters from the Anaconda and St. Lawrence mines, he noticed that tin cans thrown into the water disappeared, leaving a dark-red sediment in their place." Quite an observant person, but that simple fact had also been observed and reported by one Diego Delgado, elsewhere, in the year 1556!

The third paragraph makes manifest that William Ledford, in 1901, "was the first to put copper precipitation on a business basis"! This is the class of 'scientific-historic' rubbish served up to us by Floyd Bushnell, of California [!] in his 'dichoso' article. It may be advantageous, if not interesting, to your readers to know what the records of Spain, of mining science, have to say about this same "production of copper by precipitation" through the employment of 'mine-water', or vitriolous liquors. It is to be surmised that the writer of that article does not make reference only to California [!] for the ultimate paragraph contains a more or less detailed notice about the precipitation or cementacion of copper liquors at Rio Tinto, in Spain.

It is sufficiently well known in Europe that this process of the precipitation—in Spanish *cementacion*—of copper contained in vitriolous waters was patented and practiced at Rio Tinto as early as the sixteenth century. And yet we are now told through the medium and substantial authority of the estimable and widely read *Mining and Scientific Press* that it was discovered by a Welshman a few years ago in North America!

According to the Official Record, the following operations took place at Rio Tinto on the 9th of May, 1752, and following days (translated):

"Note of iron placed in the *cauales* or cementation tanks on that day at 12 o'clock noon and on the following days:

	Arrobas.	Libras.
'Planchuela de Viscaya.' Sheet iron.....	24	1
'Hierro Viejo.' Scrap iron	6	21
Dia 10, á las 11 del dia	2	7
" 15, á las 7 de la tarde (p.m.). Sheet iron	49	2
" 16, á las 7 de la mañana (a.m.). <i>idem</i>	3	14
" 19, á las 7 de la mañana (a.m.). <i>idem</i>	23	24"

The well recorded history of this process may be recapitulated thus: Basil Valentine, who wrote about 1500, in his instructive *Curus Triumphalis Antimonii*, indicates this method of the extraction of copper.

It was in practice in the Lower Hartz until the middle of the sixteenth century, when it was substituted by another process, as took place at the Mines of Rammelsberg on the banks of the Okar.²

Alonzo Barba³ describes this process as it was in operation in Peru before the year 1637.

In 1661 a *licencia* was granted by the Crown⁴, at Madrid, to Alvaro Alonso de Garfias; whilst in the year 1695 a similar privilege was conceded by the same authority to Rogne Salas y Ulloa: to extract the copper from the vitriolous waters of Rio Tinto.

The same process, or the precipitation of the copper contents of 'mine-water' by placing iron in it, has also been treated of and described by Hermann, Figueroa, Heron de Villapose, Guenyevean, and others.

¹Efiguer, *L'alchimie et les alchimistes*.

²Schlutter, *De la fonte des Mines*, Vol. 2.

³Alonzo Barba, *Arts de Met.* 1, 121.

⁴Nash, 'Hist. of the Rio Tinto Mines,' p. 140.

And now we are informed, in 1911, bluntly and dryly, that a *Welshman* was the discoverer of the process of precipitation of copper by iron, in California [!] in the year 1880! And as to Ledford's being "the first person to put copper precipitation on a business basis", from 1788 to 1799 some 185 tons of copper precipitate were produced at Rio Tinto; from 1800 to 1828, 497 tons; and from 1829 to 1849, 3166 tons of precipitate, by this same process. At the same place the product of the years 1849 to 1862 was 5104 tons of precipitate, and from 1862 to 1872, about 10,193 tons. The last paragraph of this article contains the very venturesome affirmation "that the water (of Rio Tinto) runs as high as 0.2 and 0.3% of copper." But if that implies a distinction of class of cupriferous waters, then to what two classes does he allude? There necessarily are various classes of copper liquors—'mine-water' is the happy phrase of Mr. Bushnell—all of various grades of percentage of copper.

But what is equally surprising is the allegation made also in the last paragraph of the article under examination, that "the water from the Rio Tinto mines, after having run through the precipitating plants, is as strong as the water coming from the Butte mines." Presumably he means us to infer, as to these latter, in their untreated state. This is quite in harmony with the other allegations. But if that actually is so, then the shareholders of the Rio Tinto company can with good reason charge the local management with a wicked waste of copper: for the inference is that a certain quantity of copper is daily being lost because of unskillful treatment and of wasteful supervision! But fortunately for their pockets, and, too, for the credit of those engaged in the huge work of cementation or precipitation as at Rio Tinto is performed, *that is not so*. The final passage: "that the water (at Butte) after it passes the last precipitating plant, shows the exceedingly small percentage of 0.0002 of copper", should be very satisfactory to the Butte interests—if *that actually is the case*.

W. G. NASH.

Minas de Rio Tinto, Spain.

[Our correspondent's letter is of so much interest and contains statements of so much value that it can scarcely be regretted that the limitations of his knowledge of American geography and local history have led him into some misconceptions regarding the article in question. Mr. Bushnell's opening paragraph disclosed the fact that he was discussing copper cementation at Butte (a place which, we may add for the benefit of our correspondent, is in Montana, as far from California as Rio Tinto from London). There, strange as it may seem, the cementation process was for some time actually unknown, though it had been so long practised elsewhere. The history of the early mining and metallurgical development of American mining districts is, in many cases, only preserved in the memories of the pioneers, who frequently disagree as to details, but there seems little doubt a citizen of Butte, knowing that copper could be precipitated from its solutions by the use of metallic iron, actually discovered the feasibility of precipitating metallic copper from the water which had for years been pumped from the mines of the Butte district and allowed to escape. The apparent analogy between this and the work at Rio Tinto dissolves upon close examination: in the latter case the operator is dealing with a comparatively strong liquor resulting from metallurgical operations, while in the former a dilute natural solution, relatively free from the arsenic, antimony, and bismuth which interfere with complete precipitation at Rio Tinto, is employed. It is well known that the *salida* which is allowed to run to waste at Rio Tinto contains an appreciable percentage of copper, and it should be equally obvious that it is thus allowed to escape because, under the local conditions, it is uneconomical to attempt a more complete precipitation. Mr. Bushnell's paper is of much value because of the quantitative statements regarding Butte practice it contains, and we hope that those of our readers who are in possession of such data will correct any errors of fact, if such exist.—EDITOR.]

⁵*Ibid*, appendix.

Conservation of Investments in Gold Mines

The Editor:

Sir—I have read the criticism by Charles Janin in your issue of December 16 on my article which appeared in the issue of December 9. In the criticism the conservation of dividends in the protection of capital by a mining directorate is deprecated: in fact, Mr. Janin states that such a policy is usurping the function of those authorized by the laws of the land for the protection of imbeciles. The substance of the criticism is evidently the idea that an investor in a mining company has the right to look after his own money and the profits therefrom. Such an idea is theoretically ideal, but, like innumerable other theoretical ideals, it is sadly wanting in practical application. A mining company is not a mechanical collection of units in the shape of shareholders: it is a unit in itself and a policy that conserves the welfare of this unit will likewise conserve the interests of the component parts. Without presuming on the space of your serious paper, by the use of such sarcasm as Mr. Janin employs, I might briefly point out that our viewpoints are far from coincident. That of Mr. Janin is evidently from the little shareholder, thence to the public company. I believe the welfare of the company is primary, and if competently managed and its capital amortized the industry from a broad viewpoint is benefited and, as a *sine qua non*, the collective and individual interests of shareholders.

The Oroya Brownhill during its productive life built up a cash reserve of over \$2,000,000. This property, as those interested in English mining companies will know, was one of the most famous gold producers in Australia. When its ore resources became curtailed, these funds were applied to the purchase and development of two other properties, the Oroya Black Range and the Oroya Links. The success of these latter enterprises can be substantiated by a little investigation. The exhaustion of the orebodies of the parent mine was, therefore, countered by the substitution of two other mines of present earning power and indications of future life. The Camp Bird mine is now practically exhausted, but the prospect of the successful continuance of the company, Camp Bird, Ltd., is excellent: the large cash reserve being utilized in the purchase of the Santa Gertrudis mine. Instead of the shares being quoted as worthless, as is usual with most mining enterprises when their ore resources are exhausted, or nearly so, the present market valuation of the enterprise is well over 50% premium. The book value of the holding of Camp Bird, Ltd., in the Santa Gertrudis Company, Ltd., is estimated at approximately \$5,700,000. The Progress Mines of New Zealand have pursued a similar policy, having re-invested in the well known Blackwater mine, together with other successful investments.

Such a policy of capital conservation has many significant features of attraction. The existence of an experienced directorate and a tried engineering staff is a point that will appeal to any business man. The efficiency of the engineering staff in starting up new work, when expensive mistakes are frequently made, is paramount. When new work is started by a newly-organized staff, the personal equation of each member of which is unknown to the others, efficiency is almost impossible and the liability of expensive mistakes is in proportion to the gravity of the work to be undertaken. There is also a great disproportion of the time required to obtain results, irrespective of the question of mistakes. I believe this is one of the prime causes of mining failures, and its significance cannot be overestimated. On the other hand, new work under an experienced general manager who is in harmony with his directorate and who knows the relative capability of the members of his staff from previous experience, is started and completed with a minimum of time and expenditure producing maximum results. In a word, the organization, collectively and individually, is efficient, having numerous experiences and precedents to guide it successfully.

Mr. Janin then goes on to discuss the relative difference in issuing stock at its par value with the common practice

in the United States of issuing at a discount depending on risk. I fail to see what bearing this subject has on my article, which was on capital amortization. Which is the better is evidently pretty much a question of the relative features of salesmanship and has nothing to do with the subject. I regret that, owing to my absence in Europe, I have been unable to reply at an earlier date.

MORTON WEBBER.

New York City, January 12.

The Editor:

Sir—Mr. Webber contends that while the right of the investor in mining companies to look after his own money is theoretically ideal, his ability to do so is sadly wanting in practical application. He criticizes me for suggesting that even if this is so it is not the special function of a mining directorate to usurp the right to become guardians to the incompetent shareholders, yet he implies that once an investor puts his money in mining shares he should become the ward by adoption of the directors. Also, Mr. Webber evidently believes that a distinction should be drawn between the small shareholder and one more heavily interested; whereas one of the fundamental principles of a corporation is that each share shall be on an equality with all the other shares, and that each shareholder shall benefit equally with all other shareholders in proportion to his holdings. Of the relative advantages to be gained by investing in those mining operations which are under competent technical direction as compared to those in the hands of the inexperienced discussion is unnecessary. It is obvious even to the sarcastic. On the other hand, an incompetent directorate is hard to oust, especially in a paying company, and the same applies to the staff. The experience of an efficient staff can, however, be utilized in new ventures by those who wish to participate in those ventures. The basis of contention in this discussion is whether when on becoming a shareholder in a mining company, the investor does so with the idea of securing the resultant profits from its operations, if any, or if he is simply subscribing in a blind pool, the profits from which may be used for the purpose of perpetuating the company as a whole, and for the possible benefit of those in control of the management.

The investor in a mining company often invests solely upon his own judgment as to the physical valuation of his holdings, or upon the judgment of some one upon whom he professionally relies. He assumes that the property in question will be as skillfully handled as at the time of his investigation, and that the profits will be distributed to the shareholders, and it is upon this assumption that he bases his valuation of the shares. Chance may have favored the company, yet he may place no reliance in the judgment of those in control to acquire other property, and be unwilling to participate in an exploration company carried on under their direction. And Mr. Webber's proposal is tantamount to making each mining company an exploration company. The primary idea of a mining company is a body of adventurers joined together for some specific purpose, upon the completion of which the company is resolved into its constituent parts with division of assets, if any exist. Mr. Webber's scheme is to keep a successful company going. This would certainly appeal to the promoters and directors of a successful company, who could then have their good fortune as a tangible asset in future promotions.

As to the examples cited by Mr. Webber, I fail to see in any instance that he has demonstrated that the directors have invested the profits of their respective companies more wisely than the shareholder could have done on his own account if they had been distributed in the first instance. The articles of incorporation of one of these companies provided for a high rate of remuneration to the directors, and they were no doubt not averse to benefiting by this clause by investing their shareholders' money, in order to continue participating in the profits, where they could not hope to get so favorable

a clause in the articles of incorporation of any new company formed. The recent criticism of the method of financing the new holding of another of these companies would seem to indicate that had not certain persons holding fiduciary relationship to the holding company participated by taking intermediate profits, the purchase price of the new property might have been substantially less than the price paid.

CHARLES JANIN.

San Francisco, January 30.

Gyratory v. Jaw Crushers

The Editor

Sir—Can you refer me to any reliable comparisons between the two types of ore or rock crushers, gyratory and jaw? I cannot find anything comprehensive along this line.

San Francisco, January 25.

[The best data on the two types of crushers available may be found in Richards 'Ore Dressing', Volume I. There is room, however, for much additional data. It is difficult to get a direct comparison, for the reason that both types of crushers are not generally used in the same mill and under the same conditions. The best chance for comparison is where in rebuilding, one type has been replaced by the other. Summarizing the experience of three engineers, each having used both styles of crusher, it may be said that for large capacities the gyratory has the advantage of a lower capital cost for actual tonnage handled; ordinary renewals are not greatly dissimilar; extraordinary repairs on the gyratory may offset largely, if not entirely, its other advantages. The trouble arises from broken spindles. It is difficult to secure steel shafting of the quality needed for this use, and breakage is markedly irregular. A given spindle may last a long time, only to be replaced, when finally broken, by a rapid succession of imperfect ones. On this account, costs averaged over a short period only may well be especially deceptive. It is none the less significant that practically all of the large new plants include gyratory crushers.—EDITOR.]

Mount Boppy Gold Mine, N. S. W.

The Mount Boppy mine is well known as the premier gold producer of New South Wales, but it is common knowledge that the treatment methods in use for many years have been hopelessly out of date, and very wasteful. Although the lode is large, it has contained some rich ore-shoots of gold. The oxidized portion of the lode is free-milling, and fairly well adapted to amalgamation and cyanidation by sliming. The sand, when treated by the cyanide process, never gave a really good extraction, the residue always having a fairly high gold content, and was used for filling up the stopes. The slime always gave a good extraction when consisting of oxidized ore only. Sand containing \$2 to \$2.50 per ton is said to have been freely used for stope-filling. The sulphide portion of the vein contains a small amount of free gold, but it has not yielded a good extraction by cyanide treatment, either in the form of sand or slime, especially when the original value was high. The company is now busily engaged with the erection of an all-sliming plant on the Moore vacuum system. It is understood a royalty of 6d. per ton has to be paid, but, notwithstanding this, it is hoped that the results will show a considerable improvement. *Mining and Engineering Review.*

As the oxygen in air diminishes, the flame of a candle or lamp is affected in two ways. In the first place, the light emitted steadily diminishes. Roughly speaking, the light of a candle or lamp diminishes by 30% with a fall of 1% in the oxygen content, and the flame will no longer burn when the oxygen has fallen from the normal (20.93%) to about 17.5%. A further effect is that the flame becomes less and less stable and it is more and more easily blown out by any chance draft or movement.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

DAHLITE is a mineral, found in Norway, approximating apatite in composition, but containing small amounts of CO_2 and water. The formula $2\text{Ca}_3\text{P}_2\text{O}_8 \cdot \text{CaCO}_3 \cdot \frac{1}{2}\text{H}_2\text{O}$ has been assigned to it.

A FREQUENT cause of explosions in compressed air discharge pipes and receivers is an accumulation of carbon in the pipes or of oil in the receiver. Oil should be drawn off from all air receivers at frequent intervals.

THE first census of the Panama Canal Zone was taken from March 3 to June 23, 1908, and showed the population of be 50,003, of whom 24,296 were employed on the Canal or railroad work. This did not include the employees living in Panama and Colon. The whites numbered 14,635, the blacks 34,785, and the yellow 583.

OBJECTIONS to the use of reinforced concrete for certain classes of buildings are that where it is necessary to make frequent changes, alterations, and repairs, and in fact in any structure that is not intended to be permanent for many years, it becomes very costly. When it has outlived its usefulness, it is expensive to remove and the materials have little or no value.

ALTHOUGH many beds of gravel are found where suitable clean material for concrete work may be obtained, it is more often the case that clay and loam are mixed with the gravel in excessive proportions. These substances form a coating on the stones and pebbles which prevents the cement from forming an intimate bond with the stone. The strength of the concrete thus has only the strength of the cement, losing a great deal of the value of the aggregate.

UNTIL recently, with rare exceptions, shaft bottoms have been lined with timber only. Such mine timbers, if of white oak, last five to eight years, depending on whether the natural conditions foster dry rot, and if of black oak or white pine, shorter periods. As the cost of replacing such timbers is greater than their first cost, when a mine lasts over twenty years it is manifest that wood timbering is in the long run more expensive than reinforced concrete and there is always the great danger of its taking fire.

LEAD, when present in bullion, is best oxidized by nitre or sal-ammoniac; tin, by means of potassium carbonate; antimony and arsenic, by means of nitre or stirring with an iron rod. Sodium carbonate is to be avoided unless there is silicious matter present; still, a little of it with nitre seems to work well, even if the bullion is quite pure. Bone-ash and silica save the crucible from the action of the oxides, and are especially useful in thickening slags in case thickening is necessary. If bullion is poured together with slag, it should be perfectly liquid.

SULPHUR is of use both directly and indirectly to almost every individual, for it touches vitally the fertilizing industry in an indirect way, and fruit growing more directly. In the form of pyrite it is extensively employed in the manufacture of sulphuric acid, which is largely used in the manufacture of phosphate fertilizer. An immense quantity of sulphur is used in bleaching wood pulp, the chief raw material of our newspapers. Match manufacturers, powder makers, sugar refiners, and makers of rubber goods all use it, and as a drug it is well known.

THE 'Cassel Gold-Extracting Process' depended on the solvent action of chlorine generated electrolytically in an alkaline solution. It was found, however, that such

solvents attacked the base metals in the ore in preference to the gold. Attempts were made to dissolve the gold and limit the action on base metals by adding chlorine or bromine, without the electric current, and introducing a salt which would neither absorb Cl or Br, nor precipitate gold, but which would precipitate base-metal compounds. The process was investigated in 1886 by a research syndicate, which directed its efforts toward finding a gold solvent which would not dissolve base metals, and the MacArthur-Forrest cyanide process was the outcome of their efforts.

MONUMENTS and markings of a claim in the field will control over the stated courses and distances in the location notice when the two disagree. If the claim as monumented conforms with the requirements of the law to the size and shape and marking of a claim, it is entirely valid. Thus, where the location notice calls for given distances "easterly" and "westerly" from the point of discovery, but the monuments define an L-shaped claim, if the claim as marked conforms to the requirements of the law, it is entirely valid, as against any subsequent locators.

RIGHT of one stockholder in a corporation to access to a list of his fellow-stockholders with their registered addresses, has been affirmed by the Supreme Court of Maine. The Maine statute requires corporations organized under the laws of Maine to keep such a list upon file in the clerk's office in Maine. The San Toy Mining Co., it is complained, first filed a list without addresses, and later when the addresses had been supplied, ordered its clerk to refuse access to the list. This right of access was enforced by mandamus. State statutes on this point differ. New Jersey assesses a fine against any corporation official refusing the information when duly requested.

STANDARD screens, according to the recommendation of the committee appointed for that purpose by the Institution of Mining and Metallurgy, should have a screening area of 25%. This cannot exactly be attained in practice, because of the mechanical difficulties of manufacture, and because the standard sizes of wire do not exactly fit these specifications. Thus a 20-mesh screen, with 0.025-in. wire and an opening of the same size, has exactly 25% screening area, as has a 100-mesh screen with 0.005-in. wire and opening. But a standard 30-mesh screen, with 0.0167-in. wire and 0.0166-in. opening has 24.8% screening area, and an 80-mesh, with 0.0063-in. wire and 0.0062-in. opening has 24.6% screening area. But these differences are much smaller than the experimental errors which occur even in the most careful screening work. Standard screens, which can easily be obtained, should always be used in screening tests.

THE states which are spoken of as the mining-law states, for the reason that the mining law is in daily use in them and that they are generally assumed to be the whole field of American mining law, are California, Oregon, Washington, Idaho, Montana, North Dakota, South Dakota, Wyoming, Colorado, Utah, Nevada, Arizona, New Mexico, and the District of Alaska. It will be noticed that they include, besides the Rocky Mountain and Pacific Coast States, the Dakotas and Alaska. Of the remaining states, many never had any public domain; to others the mining laws were not extended or were subsequently repealed. The law has some force and utility in Arkansas, Florida, Louisiana, Mississippi, and parts of Oklahoma, but owing to the almost total absence of public mineral land in those states, they need not be considered. Texas having joined the United States as a sovereign power, retained possession of her unoccupied unclaimed land, enacting a state code of mining laws to govern them. For the Philippine Islands special mining laws have been provided. The possessions of the United States outside of Alaska and the Philippines have no mining laws.

Special Correspondence

MEXICO

HEAVY FOREIGN INVESTMENT EXPECTED IN MEXICO.—DOS ESTRELLAS HEADS LIST OF COPPER PRODUCERS FOR 1911. GENERAL NOTES.

Mining men generally are optimistic concerning the immediate future of the mining industry in Mexico. The present favorable prices of silver and copper encourage mining activity, and it is believed that the danger of serious disturbances has passed. Plans that were delayed by the political upheaval of a year ago will be carried out this year, and the investment of much foreign capital is expected. Several deals of importance are pending.

The Dos Estrellas mine in the Talpujahua district of Michoacan—generally referred to as an El Oro property—continued to hold first place among Mexican producers during 1911. The year's production was about \$11,000,000, and the dividends paid in the twelve months totaled \$6,000,000. Figures covering 11 months show a production of

MEXICO MINES OF EL ORO.

\$10,067,698 from 435,317 tons of ore milled, and profits of \$5,563,488. The best monthly record was in June, when the revenue from 47,705 tons of ore milled was \$1,175,121 and the profit \$675,051. In March and September, also, the revenue was over a million pesos. The four principal concerns of the El Oro section—Dos Estrellas, El Oro M. & R., Esperanza, and Mexico Mines of El Oro—had a total production in 1911 of about \$20,000,000.

Greene-Cananea closed the year with a December production of 3,706,000 lb. of copper, a slight increase over the production in November. According to a Cananea report, L. D. Ricketts, general manager, has announced that arrangements are being made for the early payment of a dividend, but the proposed rate is not stated. Greene-Cananea now is producing copper at about 9c. per lb., and at its present rate of production and the present price of the metal the earnings are sufficient for a substantial disbursement. The issued stock of Greene-Cananea amounts to 2,500,000 shares, par value \$20. The 1911 production of the Moctezuma Copper Co. (Phelps-Dodge) was 25,512,558 lb. of copper, as against 22,659,651 lb. in 1910. The December output, 2,864,464 lb., was the largest of the year. An important announcement in connection with copper production in Mexico is that the railroad to be built from Balsas, the terminus of the Cuernavaca division of the National Railways, to the Pacific ports of Zihuatenejo and Acapulco will include a branch to the Iguanaran copper mines in Michoacan, and that a smelter will be built. These mines are controlled by the Paris Rothschilds, who also control the Boleo copper mines in Lower California, and they have been extensively developed. The concession for the railroad was recently granted the Mexican Pacific Co., of

Seattle, Wash., which has been building between Acapulco and Zihuatenejo under a previous concession. When the time for production is reached, it is expected that the Iguanaran mines will contribute substantially to the copper output of Mexico.

Announcement is made that the Doheny oil interests have entered into contracts covering the sale for future delivery of about 55,000,000 bbl. of Mexican oil, and that it is expected to receive an average price of 48c. per bbl. Deliveries under contracts during the present year will average 24,000 bbl. of oil per day, and the gross earnings from these deliveries are expected to total \$4,200,000. The Doheny interests have storage for about 8,000,000 bbl. of oil, and this will be increased to at least 10,000,000 bbl. The possible production of the present wells is estimated at from 60,000 to 70,000 bbl. per day. The Doheny holdings aggregate about 600,000 acres of land, 75% of which is owned, and the remainder held under leases. The investments to date total about \$7,500,000. The principal Doheny companies are the Mexican Petroleum Co., Ltd., of Delaware, a parent organization, and the Mexican Petroleum Co. of California, and the Huasteca Petroleum Company.

NEW YORK

HAS THE 'COPPER MERGER' BEEN ACCOMPLISHED?—GREENE-CANANEA DIVIDEND.—PORPHYRY AND PLACER NOTES.—ENGLISH SHARES POPULAR.

The possibilities which lie in the coming together of the larger banking interests that are interested in leading copper properties has formed one of the chief topics of interest among mining men during the past fortnight. Many profess to see in the underwriting of the bonds and stock of the Inspiration Consolidated Mines Co. by J. P. Morgan & Co., and in the grouping of factors in the copper world around the directors' table of that company, the practical achievement of the much-talked-of copper merger. If this is what has in reality been accomplished, it is truly a most important, even epochal, movement in copper mining. From a Wall Street point of view such a substitute for a flotation which was to do for copper what the United States Steel Corporation has done for steel, is by no means satisfactory. The share markets in the East have for a long time needed a new leader, and such a leader as would appeal to that general public which has forsaken the Street very largely. Wall Street has for some time been in a frame of mind where it would give its kingdom—not for a horse—but for a lead mule. The course of events since the first of the year has marked even more emphatically the prevailing lack of public support. During the latter half of December and through the holiday season there was an obvious marking up of goods upon the shelves, prices were advanced, and a generally brisk business air assumed as far as possible, all in preparation for the semi-annual distribution of dividends. The latter half of January discloses the market dropping once more into dullness such as is supposed to come only in hottest midsummer. If into the prevailing stagnation there could be brought a new leader, especially one with which people at large are as familiar as they are with copper, it would be most welcome. If copper interests are to get together without any fanfare of trumpets, without any big distribution of securities, the financial centres will count it an opportunity lost.

The Greene-Cananea dividend has been announced; 25c. per share is to be paid March 1. The Greene-Cananea is purely a holding company, and the payment of the present dividend is made possible by dividend payments upon the part of the old Greene Consolidated Copper and the Cananea Central Copper Co., the two subsidiaries of the Greene-Cananea. Each of the operating companies is paying 60c. per share, making a total distribution of about \$960,000. Of this amount, some \$30,000 goes to those rebellious holders of Greene Consolidated who have refused to exchange the old stock for that of the holding company. The Greene-Cananea company will in its turn

distribute some \$606,000 and retain some \$320,000 in its treasury. The present dividend will be the first payment made to Greene Consolidated shareholders since 1907. W. E. Corey, former president of the United States Steel Corporation, has been elected a director of the Greene-Canaan, to fill the vacancy created by the resignation of "Cap'n Jim" Hoatson.

The final meeting of the shareholders of the Butte Coalition was held in New Jersey last week, and the certificate of dissolution has been filed at Trenton, New Jersey. The Butte Coalition Co. was one of the most important stepping stones in the path of John D. Ryan and Thomas F. Cole, and its formation was the direct result of the efforts of Messrs. Cole and Ryan to patch up peace with Heinze and terminate the appalling snarl of litigation, which involved nearly every important and many unimportant properties in Butte and had so far passed beyond the control of the courts as to almost preclude the possibility of adjustment by such tribunals. All of the Butte Coalition assets except the Anaconda stock and the cash in the treasury having been already administered upon, there remains for distribution some 52 shares of Anaconda and some \$441 in cash to go to each holder of 100 shares of Butte Coalition.

The Lake copper country is enjoying increased interest in developments at two or three properties. At the Victoria, which is the oldest of all the Lake properties, the first work, by white men, having been done on that ground in 1771, operations are pointing to the opening up of a large territory heretofore considered as of no particular value as mining ground. The Mayflower and the Old Colony are looked upon as large possibilities in the near future, perhaps to furnish material for market operations similar to that which followed the opening of the amygdaloidal bed in the ground of the Lake Copper Co. The upset suffered in the plan to consolidate all the subsidiaries of the Calumet & Hecla had a depressing effect upon the Boston market for copper shares, and some new live issues with attractive speculative possibilities will be heartily welcomed by Boston traders.

The underwriting which J. P. Morgan & Co. has assumed for the Inspiration Consolidated Copper Co. consists of \$30,000,000 in stock and \$6,000,000 in convertible bonds. The shares of the old Inspiration company are being exchanged for the shares of the new company, on the basis of two shares of old stock for one of new, and Live Oak is being exchanged on the basis of two shares of the new company for one share of Live Oak. This is calculated on a basis of \$10 for Inspiration and \$40 for Live Oak, and shareholders are given the privilege of making sale of the stock at these prices instead of exchanging if they so desire. Notwithstanding the importance of the announcement and concerted action recently put forth to make a boom in copper metal, and indirectly in copper shares, the upward turn seems to have reached its utmost height, and prices of both the metal and the shares are inclined to sag. The shareholders of the Ray Central Copper Co. have approved the issue of \$1,800,000 convertible 6% bonds.

The La Grange Placer Mining Co. has been organized to take over the La Grange M. Co., a hydraulic property in Trinity county, California. The La Grange M. Co. was operated as a close corporation and is claimed to have been one of the largest hydraulic mines in the world. The late Robert S. Mather, head of the Chicago, Rock Island & Pacific railway, was president of the company. The shares of the new company are to seek an active market on the New York curb.

One of the features of the mining market in New York is the activity in American mining properties which are under English management and which are traded in on the London Stock Exchange. These shares enjoy a strong following on this side of the water, due in no small part to the fact that investors can keep closely in touch with mining operations and can see a monthly report without having to invoke extreme legal proceedings to learn what is going on. The recent rapid rise in Esperanza, due to some favorable

developments on the eleventh level, created quite a little interest and a fair volume of business. There is a constantly growing body of investors who like the speculative feature of mining enterprises, but who are no longer willing to go into 'get-rich-quick' and doubtful schemes, and who have learned to like the English method of mining operations.

The collapse of the Porcupine excitement is a patent illustration of how far the public has become educated in mining finance. Canadian business has suffered so far as to cause the temporary closing of the exchange in Toronto, and it is quite evident that whatever remains to be done in the Canadian gold district that has been so much in the public prints, is to be done without any support from the outside investor.

The trial of George Graham Rice, in the Federal court, charged with conducting a bucket shop and using the mails for fraudulent purposes, drags along without further incident than the rupture between the principal defendant, Rice, and the attorneys in charge of the case, and the attempt by Rice, who is nothing if not versatile, to conduct his own defense. It was found necessary, in the interest of expediency, to appoint counsel for the defendant, and the case resumed its slow progress.

BLACK HILLS, SOUTH DAKOTA

DEVELOPMENT NOTES.—GRUBSTAKING CONCERN INCORPORATED.—HOMESTAKE MAKES NEW RECORD FOR PRODUCTION.—ANNUAL REPORT.

Wood brothers, of Montreal, have secured options on the Hidden Fortune and Columbus properties, and a systematic examination of the orebodies is now well under way. The unwatering of the two shafts has been started, at the Hidden Fortune by means of pumping, and at the Columbus by skips. The first-named shaft is 300 ft. deep, and the latter 500 ft. At the Columbus the workings are extensive on the 200 and 500-ft. levels. In addition, drifts, test pits, and shallow shafts are being sampled. Further development work is planned for both big shafts in mining and diamond-drilling. Two diamond-drills have been delivered, one at each shaft, and several thousand feet of drilling will be done. Both shafts are equipped with good steam plants; each has a double-drum hoist, air-compressor, and shop. The samples are being handled in an assay office which was fitted up in Deadwood. It will be necessary to make several thousand assays in the course of the work. The work is in charge of A. M. Howat, of Los Angeles, who is assisted by John Muir and Roy H. Clarke, who are taking the samples, and H. D. Whitehouse, who has charge of the assay office. The property under examination totals about 1000 acres and adjoins the Homestake on the west and north.

After several months work, sinking is to be discontinued and lateral work undertaken, at the North Homestake shaft, at Maitland. A station now being cut is at a depth of 620 ft. below the surface, or 400 ft. below the point where sinking was commenced last summer. A deep sump and good-sized station will be cut, and cross-cuts will be driven east and west to intersect veins disclosed in diamond-drilling. The Golden Crest company has levied an assessment of 10c. per share upon the stock issued. A movement is on foot among the stockholders to reduce the capitalization and get the affairs in shape for financing the property, so that operations can be undertaken at the mine. The property is equipped with a 40-stamp mill, thoroughly modern, and one of the best plants in the Black Hills, but internal difficulties arose about the time the mill was completed, and it has never handled any ore whatever. Earnest efforts are now being made to straighten out the difficulties, and to raise money to take care of indebtedness and judgments.

The Black Hills Smelting Co., owner of the new smelter being completed at Galena, has taken a lease from the Golden Flat company on the Hardin mine in Two Bit gulch. This mine contains a large body of pyritic ore, some of which carries much gold, and it is planned to haul the

ore in wagons to the Gilt Edge-Maid spur, in Strawberry gulch, and ship by rail the remaining three miles to the smelter. The shaft will be unwatered as fast as possible. Good progress is being made toward completion of the smelter, and since the middle of January weather conditions have moderated so that it is possible to expedite construction. The Black Hills Grubstaking Concern has been incorporated, and it is proposed to raise locally \$20,000, which will be enough to grubstake 100 prospectors for one year. The commercial clubs of Lead, Deadwood, and Rapid City are interested, and will receive and act upon applications for grubstakes from the prospectors in their respective localities.

Homestake produced bullion valued at \$6,040,000 during the year 1911, the largest year's production in its history. During the same period it paid dividends amounting to \$1,310,400, making a total to and including December 25, of \$27,539,040. Ore milled during the year amounted to 1,514,035 tons, so that the average recovery was \$3.92 per ton, and dividends \$0.865 per ton. Besides these large dividend disbursements, the Spearfish hydro-electric plant and other improvements cost a great deal of money, so that the actual profits were considerably above the dividend requirements. In order to conform to the Government corporation tax law, a report must be made at the close of the calendar year, so the fiscal year of the corporation was changed to close on that date instead of June 1. The report to stockholders, which will soon be issued, will cover the period from June 1, 1911, to December 31, 1911.

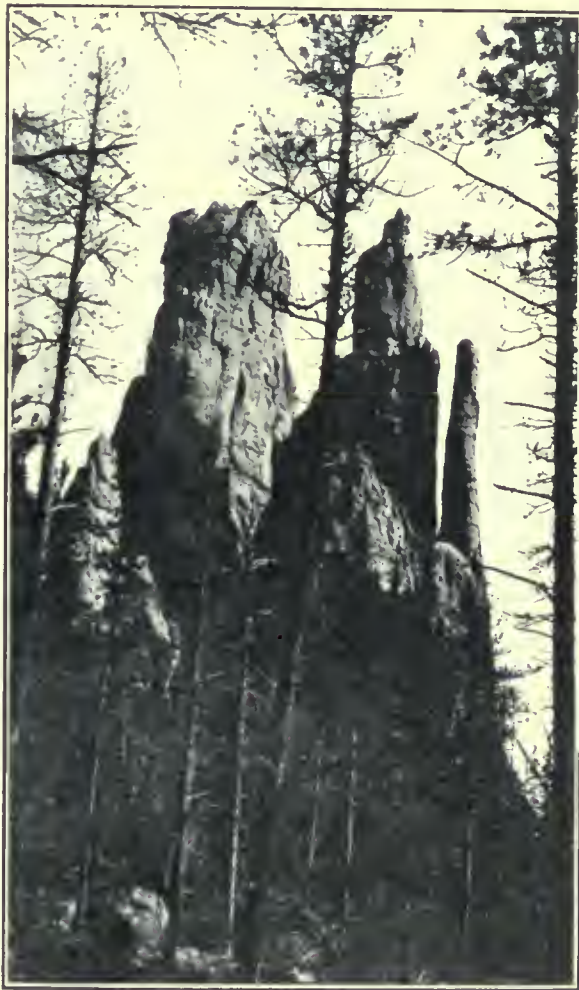

BUTTE, MONTANA

ANACONDA NOTES.—BUTTE & ELY ELECTION.—DEVELOPMENT AT THE STEWART.—PROGRESS AT PILOT BUTTE.

From present appearances it would seem that practically every branch of the Anaconda Copper Mining Co.'s industry will be operated by electricity within the next twelve months. The latest announcement is that the company road running between this city and Anaconda is to be operated by electricity. It is estimated that the expense of changing the Butte, Anaconda & Pacific railroad from steam to electricity will be about \$1,000,000. Including side-tracks and lines running in and around the mines, the railroad has 114 miles of track, and the whole system will be ready for operation in about one year. Seventeen motors will be required to operate the passenger and ore trains, and the only difference in them will be that those employed in the freight hauling will be geared differently from those engaged in running the passenger trains. Before deciding on the system to be used, much time was devoted to an investigation of the trolley and storage-battery systems, and the trolley system was adopted. The power for operating will come from the Great Falls line, which was built to this city for the purpose of supplying the mines and the smelter at Anaconda with power. A thorough test was made and the conclusion was reached that there was enough power going to waste to more than meet all that was required to operate the railway.

The Duluth men won out in the annual meeting of the Butte & Ely Copper Co. which was held in this city a few days ago. There was some apparent friction between the Butte directors and those from outside, but it was only over a question of policy, and everything was adjusted later. J. B. Cotton, of Duluth, president of the company, was unable to come to the meeting, and he sent John W. Neukom, an attorney, with full power to represent him and armed with proxies sufficient to carry out an arranged program. This seemed rather objectionable to the local men, and they wanted to delay matters for some purpose or other. This Mr. Neukom was not disposed to concede, so when a motion to adjourn for a week was proposed, he protested, but in spite of his protest the local man in the chair declared the meeting adjourned. Then Mr. Neukom got busy and called the gathering to order again. The majority of the Butte men retired, but a few remained. John D. Pope, general manager for the North Butte com-

pany, was named as chairman, and as soon as the meeting was organized Mr. Neukom proceeded to do business. He elected John B. Cotton, J. W. Neukom, and Edward Maney, of Duluth, and John D. Pope and T. B. Moore, of this city, directors. The directors afterward met and elected Mr. Cotton president, Mr. Pope vice-president, Mr. Maney treasurer, and Mr. Neukom secretary. Previous to this Roy S. Alley, private secretary to John D. Ryan, was secretary for the company. Among the matters to have been considered at the meeting was the removal of the office of the company to Duluth, but the new directors thought that this was not advisable, and held that while all the officers would be in Duluth except the vice-president, there should be an assistant secretary here, and one of the

IN THE CENTRAL BLACK HILLS

clerks in Mr. Pope's office was selected for this position. The annual report of Mr. Cotton was read at the meeting and to this a majority of the Butte stockholders took exception, inasmuch as it did not contain any definite statement as to the future development of the property. It was contended that it should have outlined some positive policy, rather than make the statement that if certain conditions were found correct, something must be done. The report showed that on January 1 of this year there was in the treasury something over \$210,000, but that since then it developed that \$100,000 had been transferred from a bank in this city to Duluth.

The ore discovered in the new adit of the Stewart mine is said to be rich and, inasmuch as the mill at Wallace is being taxed to its capacity in handling the present output of between 450 and 500 tons per day, there is talk of securing the Tiger mill at Burke, Idaho. F. Augustus Heinze, who has the controlling interest in the Stewart property, has wired that he will be in this city in a few days, and that he will proceed to the Coeur d'Alene to investigate the situation. E. J. Carter, one of the directors of the company, says that the company has been entirely out of

debt for some months and that he sees no reason why there should not be a substantial dividend paid in the near future. The Pilot Butte company has completed a station on the 900-ft. level and a cross-cut is being driven to intersect the Berlin vein. The shaft will be carried to a depth of 1300 ft. to meet the cross-cut from the Black Rock mine of the Butte & Superior company. Delay in the arrival of some of the guys for the new Tuolumne surface plant has prevented the new equipment being put in commission before this. The steam was turned on and everything found to be in good order, but it will be near the middle of the month before the plant will be in active operation. A fire which had its origin in the old St. Lawrence mine in 1889 and which has been burning ever since, got away from the fire-fighters for a short time the other day and destroyed the air-shaft of the Mollie Murphy mine. There was no other damage.

KALGOORLIE, WESTERN AUSTRALIA

LABOR GOVERNMENT ENDS ENGINEERS' SOCIETY STRIKE.—
PHTHISIS COMMISSION REPORT.—WATER PRICES.—
GENERAL NOTES.

In my last notes, mention was made of impending trouble with the Engineers' Society, which embraces fitters, tinsmiths, blacksmiths, and other skilled men on the mines. There are about 130 of them all told, and they practically tried to hold up the mining industry of Kalgoorlie by demanding time and a half for overtime, double rates for Sundays and certain holidays, and partly new schedule for all, and new agreements about apprentices. The Union would not go to arbitration, as it should have, and all simply stopped working. It was, and it was not a strike. They had no sympathy from the Chamber of Mines, the other unions, and the community generally. They were easily led out, and their demands quite out of place at the present time. The men stood out for two weeks, during which time efforts were made to come to an understanding, with little success, until a member of the present Labor Government took a hand in the matter and, it is said, practically forced the men to return to work and abide by the arbitration award when given later on. It was a case of

excluded from mines, and from a fund, on the lines of the National Insurance scheme in England, whereby the employer, employee, and Government contribute one-third each to an insurance fund, these men are to be paid certain amounts, given hospital and medical attention while necessary, and their dependents are to be kept also, in the meantime. It is suggested that affected men be placed on the land, in parts selected by the Government. The commission did not recommend that the New Zealand system be adopted at all. Regarding underground work and ventilation it remarked that where development is of temporary character, or on unprofitable orebodies, ventilating appliances are only necessary, but where along pay ore winzes should be sunk at the usual intervals for a natural draft. It is quite understood that forcing the mines to install a lot of machinery, or sink unnecessarily, would probably be too expensive and result in some closing down, and others cutting the profits unreasonably. The men are to be protected, yet this can be overdone.

At this time of the year, the Mines Department grants exemptions from working mining leases for from 19 to 30 days, depending on the remoteness of goldfields, to enable all to take their Christmas and New Year's holidays down at the coast or in other districts.

Some rather interesting tables were recently placed before the Minister for Works, by a deputation asking for a reduction in the price of water for low-grade mines within the scope of supply from the water scheme. At present, the big mines in the water trust pay \$1.68 for 1000 gal., for ordinary purposes, and 36c. for sluicing away residue; and low-grade outcrops around here yield 84c. profit, of course taking all their water from the Government. This, they wish reduced to 48c. per 1000 gal. to stimulate the working of more low-grade mines, which are mostly small. The Minister said that the scheme must be run on business lines, and was doubtful about granting the request, as, in the past, reductions to certain parties had not resulted in any increase of consumption. The water main was capable of carrying 5,600,000 gal. per day, but, owing to internal corrosion, its capacity was now only 3,000,000 gal., which was all being sold. The table referred to above showed the following:

Company.	Hunting- ton mills.	Men em- ployed.	Tons monthly.	Value per ton.	Water used, gal.	Cost per ton treated, cents.	Rate per 1000, cents.	Ore in sight, tons.
Golden Dream	1	20	1,243	\$1.80	318,000	27	84	150,000
Lone Hand	1	7	1,000	1.32	200,000	17	84	50,000
Hammans Consols	2	27	1,300	1.78	200,000	13	84	30,000
Hidden Secret	15	500	4.32	200,000	35	84	37,000
Hadden Bros.	3	18	800	160,000	20	96

the mines gradually closing down if repairs could not be made to machinery, although most of them could have worked on for a considerable time. By this action 130 men held up an industry employing nearly 6000 and supporting a community of 30,000 persons. The Chamber of Mines met the men in good spirit, and agreed to make any award retrospective to November 20. Such a business as this, with the recent stupid strike at Mr. Lyell, in Tasmania, the trouble at the Lithgow Iron Works in New South Wales, and other trifling disputes in which men are badly advised, makes one a trifle tired of Labor at times.

The Miners' Phtthisis Commission has presented its report to Parliament. It recommends that, within three months of any Act being passed, all men employed on mines in Western Australia should be medically examined for tuberculosis, and, if all right, granted certificate to that effect, while, at intervals of not more than six months, similar examinations are to take place. If any are affected, the sufferer, the management, and the authorities are to be notified, and the first excluded from working in or about mines. A Miners' Claim Board is to be formed by the appointment of Government officials and representatives of the employers and men. This board is to deal with men ex-

The above includes representative low-grade mines, all being profitable. As we are having such a dry and hot season (in fact, the past 18 months has been so) water supplies are low or run out, so the Government is doing its best to supply all mining districts near the water scheme, and sink wells and dams for parts remote from this supply.

Glancing through the reports from mines generally, I have noted satisfactory development work in the Bullfinch, Mountain Queen, and Marvel Loch near Southern Cross; the group generally at Meekatharra; the Yuanmi and Morning Star in the East Murchison; at the group on the new find at Paynesville; the Lancefield at Laverton; the Sons of Gwalia and district; Ora Banda; and the usual yields from Kalgoorlie. The Government is erecting five stamps at Mt. Egerton, sending it by way of Peak Hill; improving the battery at Marble Bar, and is making new regulations for the payment of sand and slime at public mills. A 5-stamp mill has been erected at Paynesville, the mill near Mt. Magnet has been leased and will be improved, the Yuanmi and Mountain Queen mills are almost ready, and the Associated Northern is to erect a large plant at Ora Banda on its Gimlet South Extended mine. The latter plant is practically planned out and will consist of the following, all

driven by suction gas engines; a rock-breaker for 5-ft. Huntington mills delivering pulp to a classifier, the underflow back to two 5-ft. pans, all the slime to four thickeners, then to four ordinary agitators, the agitated slime to three vacuum machines, probably of the new Ridgway type. The trials at the mine on one Huntington mill gave 6 tons per hour through a 30 by 30 screen. Of course, the ore is very soft to run through like this. The new Ridgway machine is working well at the Great Boulder, and another is to be added, having them entirely supersede the first style of filter. The gold output for November from all mines was valued at \$2,515,000, and the yields from the chief mines were as follows:

Name.	Tonnage.	Value.	Profit.
Associated	10,105	\$67,000	\$600
Associated Northern	1,602	25,000
Burbanks Main Lode.....	1,734	18,000
Golden Horse-Shoe	24,490	150,600	3,000
Golden Ridge	2,664	27,500	8,700
Great Boulder Perseverance...	20,650	119,000	13,500
Great Boulder Proprietary...	16,815	240,000	131,000
Great Fingall	5,882	64,000	11,500
Hainault	5,150	32,500	10
Ivanhoe	20,019	200,000	90,000
Kalgurli	10,740	108,500	62,900

South Kalgurli.....	9,410	60,000	11,300

* From old residue.

LONDON

PROFITS OF THE CORNISH TAILINGS CO.—G. C. KLUG'S REPORT ON THE BROKEN HILL MINE.—TASMANIA GOLD M. CO. AFFAIRS.

A few months ago I gave in these columns some particulars of the work of the Cornish Tailings Co., which was formed a year and a half ago for the purpose of re-treating the tailing dumps belonging to the Carn Brea & Tincroft mines. These dumps are practically the only ones in the Camborne district, for it has been almost the universal custom to discharge the tailing into the Red river and other streams, much to the advantage of those who re-worked the sand and slime between the mines and the sea. The tailing from Carn Brea & Tincroft was not disposed of in the same way, for the simple and sole reason that no convenient water-course passes the mines. Many people have thought of tackling these great piles, but various difficulties have stood in the way. The Carn Brea & Tincroft company has always been so short of money that it has not been able to introduce the desired improvements into the mine operations themselves, let alone provide capital for the necessary plant for re-treating the dumps. Another difficulty is that there is no site available on the spot for the plant, and in addition it has hitherto been impossible to find a suitable place to which a right of way could be obtained. The absence of a supply of water for the dressing plant has also been an obstacle. The present ventures belong to the Baillien group, identified with Broken Hill and other mines in Australia, and Arthur Richards is the manager. The treatment plant has been erected at Wheal Agar, between Camborne and Redruth, about a mile away. The first part of the journey is made by tram, but this has not been allowed to cross the high-road, so the remainder of the journey has to be done in carts. This double transfer, of course, increases costs. The plan now is to dispense with the carting and to perform the rest of the transfer by pipe-line. The first unit of the plant was designed for the treatment of 200 tons per day, but since then an additional unit has been erected, and within three or four months the capacity will be raised to 400 tons per day. The re-grinding is done in tube-mills,

of which the fourth is now being erected. The dump material assays 19 lb. metallic tin per ton, so that the content is equal to the yield at many mines in the district. But we never have known in Cornwall how these assays are made, and the fact that only 40% of the assay-value is recovered in the plant goes to show that the assay is the chemical one, while the estimates at the other mines are more often done by the vaning shovel. The 200-ton plant cost £4500 to erect. The results for the year 1911 have just been published, and I give them in tabular form herewith:

	Tailing treated	Black tin produced	Value	Total working costs	Cost per ton..	Profit
Month.	Tons.	Tons.	£	£	s. d.	£
January ...	3,566	12.9	1,257	610	3 5	647
February ...	4,470	14.4	1,472	630	2 10	842
March	4,405	16.45	1,601	672	3 0	929
April	4,890	17.75	1,705	687	2 10	1,018
May	4,314	19.55	1,902	738	3 5	1,164
June	4,954	26.75	2,408	832	3 4¼	1,574
July	4,845	25.20	2,160	846	3 6	1,314
August	4,843	23.00	2,337	878	3 7½	1,459
September ...	5,085	24.20	2,310	892	3 6	1,418
October	6,117	24.50	2,418	945	3 1	1,472
November ...	6,236	26.0	2,519	1,181	3 9¼	1,338
December ...	6,130	27.1	2,625	1,171	3 9¾	1,454

By referring to the tables of output during 1911 it will be seen that this company is one of the substantial producers of black tin and can compare with such a mine as the Levant. The profit, of course, is far higher than at any mine, and it is obvious that with a capital of only £40,000 the venture is relatively far more profitable than any other tin venture in the county. I have not been able to give you figures for the divisible profit, as the accounts are not complete. These will follow later, when I shall be able to give still further information. The dumps are estimated to contain 1,250,000 tons, which with the increased plant will last ten years or so.

One of the most important recent events at Broken Hill has been the discovery of another lode on the property of the British Broken Hill mine. Your Australian correspondent has already given particulars of this, but unfortunately the information published locally has been meagre, for the reason that the control and offices of the company are in London, and the directors do not as a rule publish such news. There was so much agitation in Australia in connection with this matter, and so many adverse rumors were circulated, that the directors decided to obtain independent advice, and not to rely solely on the views and statements of the manager, W. H. Woodhead. Accordingly the services of George C. Klug were requisitioned. Mr. Klug some years ago was connected with the Broken Hill Proprietary, so he is conversant with local conditions; and since then he has won his spurs in Western Australia as a mine manager. A cable summary of Mr. Klug's report was issued this week, and his views confirm those of Mr. Woodhead. When first published, his figures appeared to be much lower than those given by Mr. Woodhead last November, and there was an inclination on the market to consider his report unfavorable. On closer examination, however, it was found that his figures referred solely to the new lode, while Mr. Woodhead's were those of the total reserve in the mine, two very different things. Mr. Klug considers a million tons of ore as a reasonable estimate of the available ore in the new lode as far as developments have disclosed, and he quotes the average content of 15.8% lead, 12.5% zinc, and 8.2 oz. silver in the ore so far treated as likely to be maintained. People acquainted with Broken Hill conditions estimate the shareholders' profit on this ore at £1 per ton, though the editorial authorities of the financial papers here are inclined to think this figure optimistic.

General Mining News

ALASKA

KETCHIKAN

The vein on the Londevan property has been penetrated for 16 ft., and it is reported that the ore, which is silver-lead and contains some gold, will average about \$25 per ton. E. F. Moore is manager for the company.

THE TANANA

Messrs. Martin, Walters, and Sandstrom, laymen on 2 Below, left-limit bench claim, discovered ore averaging \$250 per pan, according to a recent report from Fairbanks.

ARIZONA

COCHISE COUNTY

Mike Hannon has secured an option on the Higgins mine, says a recent report, and will start development in the near future. He is negotiating for the removal of the ore through the Copper Queen property.

GILA COUNTY

Thomas Tate and associates have secured a lease on the Warrior mine. The boarding-house has been closed, and the commissary store operated by the company also will be closed.

MARICOPA COUNTY

A steam-hoist is to be erected at the main shaft of the Monte Cristo property near Wickenburg. The present equipment will be moved about 1500 ft. up the hill, where another deep shaft will be sunk. Newspaper reports state that ore from the mine occurring in 'kidneys', assays over 50% silver. Steven Loefer is driving an adit on a group of eight claims just south of the Monte Cristo.

MOHAVE COUNTY

It is reported that the Calumet & Arizona M. Co. is taking options on all properties in the Silver creek part of the San Francisco district, where it is acquiring water-power for both milling and mining. The claims under option are gold properties.

Press reports from Kingman state that J. F. Carter and Ed Schottmiller are skimming off the crust from the seepage waters that flow on their property from the tailing-pit of the Tom Reed mill. They recently shipped their first carload to the smelter, and estimate the value of the shipment as about \$200 per ton. The Tom Reed company has tried ineffectually to retain the water by dams.

CALIFORNIA

NEVADA COUNTY

(Special Correspondence.)—The Pennsylvania M. Co. is preparing to install an electric pump on the 1100-ft. level. The machine has a capacity of 500 gal. per min., with a vertical lift of 600 ft. It will be operated by a 150-hp. motor. The working force has been recently increased. The mill now comprises 20 stamps, including the 10 recently purchased and installed. It is currently rumored that considerable bonanza ore is being mined from the 1100-ft. workings of the Empire mine. The North Star Mines Co. has commenced the unwatering of the Champion and Providence shafts at the Champion group. The Worthington hoist will shortly be replaced by an electric pump, to be placed in the 1800-ft. level of the Champion, and as soon as the bottom of the 2400-ft. shaft is drained, active development from this point will be started. The north drift from the 100-ft. level of the Champion mine has been reopened. The new 5-stamp mill of the Oakman M. Co., operating near Washington, will go into commission early in February. The 500-ft. adit has opened a strong body of ore ranging from 5 to 35 ft. wide. Values average around \$450 per ton in gold and silver. Springfield, Massachusetts, people are chiefly interested. The same interests have developed promising orebodies in the Sunshine and other claims in this district. The shaft at the Marc

Antony is being sent to the 160-ft. point, whence a drift will be sent to intersect the vein. Peter Bradshaw is manager of the property, which is near Smartsville.

Grass Valley, January 29.

PLUMAS COUNTY

The Gold Queen group of placer claims, Nelson Creek district, will be sold at sheriff's sale February 16 to satisfy a judgment amounting to almost \$6000. The property is owned by the Continental M. Company.

TUOLUMNE COUNTY

(Special Correspondence.)—Experts are making an examination of the Jim Lyons mine, near Confidence. A 90-ft. shaft and a 70-ft. drift expose a 4-ft. vein of good-grade ore. A streak along the foot-wall assays \$72 to \$187 per ton.

The mill at the Republican mine, near Jacksonville, will be started by the middle of February. The ore will come from the McDougall and Mammoth claims, at both of which development work has been in progress for several weeks. Eight tons of rails just received at the property will be used in the construction of a track from the former to the latter claim. A wagon-road also is being built to the McDougall claim. Provisions, tools, and camp equipment have just been taken to the Montana King, a claim situated in the Basin district, which has three gold-bearing veins. The property is owned by James Diamond, G. G. Jahn, and Richard Whipple, all of Tuolumne. The miners from Nome who are prospecting on the Shine ranch, northwest of Sonora, have uncovered rich gravel. A rumor has it that the Confidence mine has been sold. The Sam Williams mine has been purchased by John Cassey, who proposes to develop the property.

The Trent Engineering Co., which secured the contract to remodel, improve, and enlarge the Black Oak mine plant, has this work well under way. An electric transmission line is being constructed to the property from Phoenix lake, a distance, by direct line, of about four miles. The improvements will cost about \$50,000.

Tuolumne, January 27.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—The Capital M. & T. Co. is making ready to enlarge operations. The adit, now in 5850 ft., is to be driven 1200 ft. to intersect a number of veins lying ahead of the present breast. E. Bauman is manager. L. Chairi & Co., lessees on the Paymaster mine in East Argentine, are shipping four tons per day of smelting ore that mills \$60 per ton in silver and lead. The Wisconsin and Corry City mines on Sherman mountain have been sold to H. C. Reno, representing a syndicate of capitalists. The consideration is given at \$175,000, a cash payment having been made. The 150-ton mill is to be remodeled and the machinery will be fed upon ore from the Diamond adit dump. A streak of ore 6 in. wide has been uncovered on the fourth level of the Smuggler mine that assays 761 oz. silver per ton. B. C. Catren is manager of the property. Rosenberg & Just, lessees on the Mendota, have opened a 10-in. streak of smelting ore that contains 128 oz. silver per ton. A body of ore 16 in. wide has been intersected in the west drift of the Mendota vein. Operations are through the Victoria adit. Stephens Bros. are operating under lease.

Georgetown, January 27.

(Special Correspondence.)—At the Kitty Clyde mine, G. W. Ford & Co., lessees, are making ready to repair the shaft below the adit level, where a big body of \$30 ore is exposed. It is stated that work will soon be put under way on the Seemann adit, the portal of which is situated at the base of James peak. The bore is now in 3000 ft. The Stanley L. Co. has awarded a 300-ft. contract for the extension of the fifth level westward. Within this distance the rich shoot formerly worked on the level above will be undercut at a depth of 100 ft. Work has been resumed on the Cascade property. C. Barbour is manager.

A. Ungust & Co., who have a lease on the White vein through the Commodore adit, made a shipment of seven tons of ore last week that milled 220 oz. silver. Stopping is under way on a 6-in. streak of gray copper. Work has been resumed on the Centennial mine, at Allee, of which Fred Morse is manager. Work is to be resumed on the Bonnie Briar property up Fall river, where machinery was recently installed. Henry Nimmo is manager.

Idaho Springs, January 20.

GILPIN COUNTY

A earload of ore recently shipped from the Pittsburg mine yielded 12.15 oz. gold, 15.23 oz. silver, and 13.5% copper per ton, the average value of a ton being about \$207, according to a late report. A streak of ore averaging \$50 per ton has been found in the Tyrol mine, Willis gulch, it is rumored. The main shaft on the property is down 100 ft. Operation has been resumed at the Hughes mine, Bellevue mountain, of which R. Hughes is manager. The ore is sent to the Iron City mill.

Ore yielding about \$50 per ton has been found in the Black Jack mine, Silver gulch. The shaft has been retim-

CAMP BIRD MINE.

bered. E. Perley is superintendent of the Black Jack. A shipment of ore which yielded \$20 to \$80 per ton recently was made from the Coley mine, Silver gulch.

LAKE COUNTY (LEADVILLE DISTRICT)

To promote operation of the mines on Fryer hill, the Leadville Mines Pumping Co., a quasi-public corporation, is endeavoring to finance a proposed single pumping system, relying on its income for a royalty on all ore mined from the area drained. The royalty is to be not less than 5 nor more than 10% of the net smelter returns, according to the grade of the ore. The company seeks to form 10-year contracts with all operators in that part of the district, the contracts to become void if the signatures of a large majority of the operators are not obtained within a reasonable time.

The Ibez M. Co. is shipping ore at the rate of about 3000 tons per month. Recently the zinc smelters shut down on carbonate of zinc shipments from the mine, which curtailed its production, but it now is said that by March the smelter will be in a position to increase shipments of calamine from the district.

OURAY COUNTY

High-grade ore recently was found in the east extension of the Camp Bird mine, and some miners believe that the discovery indicates that the east extension reaches the Red Mountain district.

The Jonathan dike has been intersected at the Bright Diamond claim and the ore is of good grade, according to a recent report from Ouray. Machinery has been ordered in Denver to equip the mill for grinding.

TELLER COUNTY (CRIPPLE CREEK)

The Aloha Gold M. Co. has been formed to develop the Coriolanus claim, which it has purchased, on Battle moun-

tain. The main office will be at Cripple Creek. T. B. Burbridge is president of the company. Settlement made on a earload of ore shipped by Gus Johnson from the 500-ft. level of the South Burns mine of the Acaecia G. M. Co. shows a return of \$56 per ton from the screenings and \$21 per ton from the coarse ore.

The Mary McKinney M. Co. has intersected the vein 132 ft. below the previous lowest, the seventh, level. J. N. Beatty has issued a call for proxies for the El Paso Con. G. M. Co. in the coming struggle for control of the company at the annual meeting on March 14. S. S. Bernard, former president of the company, and A. L. Burris, the incumbent, are other entries.

The Roosevelt deep drainage adit has passed the western boundary line of the Requa Savage group, and the flow of water is increasing steadily.

IDAHO

IDAHO COUNTY

The Elk City Mines Corporation will enlarge the 5-stamp mill on its South Fork mine, near Elk City, by the addition of 10 stamps. J. T. Ono, of Spokane, a director of the company, stated that the mill has been producing \$4000 in gold bullion per month since last spring.

LEMMING COUNTY

W. J. Orr, general manager for the Deer Creek M. & M. Co., announces that a reduction plant will be built on its holdings on Deer creek in the Salmon river district.

The Gilmore M. Co. has been organized, with headquarters at Salt Lake City, Utah, to take over the 12 claims formerly owned by the Allie M. Company.

SHOSHONE COUNTY

The new lower adit of the Stewart M. Co. intersected an orebody after penetrating through the Osburn fault. Importance is attached to the discovery, as indicating that the Stewart vein persists in depth. The ore was found 850 ft. from the surface.

The Hecla M. Co. has paid dividend No. 103, amounting to \$20,000, at the rate of 2c. per share. Its payment brings the total of dividend disbursements by the company up to date to \$2,370,000. The company's capital is \$250,000.

Arrangements have been completed to erect an air-compressor and a small mill on the Moonshine property at Wallace this spring. It is expected to begin shipping before the end of the year.

The Jack Waite and Black Horse mining companies, operating mines near Murray, have given a 3-year contract for their output of lead ore and concentrate to the International S. & R. Co., of Tootle, Utah.

MONTANA

FLATHEAD COUNTY

(Special Correspondence.)—Thomas D. Long, an attorney, recently filed a water right for 10,000 cu. ft. per second at the Kootenai falls. For the past three weeks engineers have been working at the falls, investigating the plan for supplying the Coeur d'Alene with power, and they will soon make their report. It is stated that \$6,000,000 will be spent in the development of the falls and that something over 70,000 hp. can be generated. Joseph A. Coram, of Boston, is interested in the undertaking.

Libby, January 29.

LINCOLN COUNTY

(Special Correspondence.)—The Montana Smelting Co., the organization which recently purchased the Snowshoe mine and other properties, now has an adit in 80 ft. on the Cherry creek side of the mountain in which the Snowshoe vein is located. This adit has been started about 100 ft. above the level of Cherry creek, and the object is to extend it until it intersects the vein under where the shaft is now being sunk on Snowshoe creek. The distance to be run is about 4000 ft. It is the intention to put in an air-compressor and power drills as soon as they can be taken into the adit.

Libby, January 24.

SILVERBOW COUNTY

The Butte Central Copper Co. has let a contract for the construction of its new concentrator to the Colorado Iron Works. The plant is to be ready for operation by June 1. The 300-ft. level orebody has been blocked out sufficiently to provide for many months' shipments.

The new compressor of the Raven Copper Co. is now in operation, and it is reported that the shaft is unwatered about to its lowest, the 1500-ft., level. Active development will be started and the property either will be placed in the producing class or, failing that, will be abandoned.

NEVADA

CHURCHILL COUNTY

The Nevada Hills and the Nevada Wonder mills have been shut down, owing to the cold weather, which interfered with the water power for the plants. Operation will be resumed, it is reported, within 60 days.

CLARK COUNTY

The Gold Legion Consolidated company has been organized to take over the four claims of the Gold Legion M. Co. and three adjoining claims owned by John Anderson. A. G. Hillen is manager for the company, which has its office at Searchlight.

The shaft of what formerly was the Black Hawk property, but which now is owned by the Rand M. Co., will be sunk to a depth of 600 ft. in the near future. A pump is to be installed. Robert Dunbar is general manager for the company.

After a shut-down of several months, operation has been resumed at the Quartette mill, of which Robert Mockbee is in charge. According to J. H. Taylor, of San Jose, California, who was sent out by J. F. More, principal owner, operation will be resumed in a short time at the Santa Barbara-Searchlight property in Eldorado canyon, including the smelter there.

ESMERALDA COUNTY

For the quarter ended November 30, 1911, the Round Mountain M. Co. mined and milled 15,936 tons of ore at a total cost of \$65,710, or \$4.12 per ton. From the 15,936 tons milled, which was of a gross value of \$90,576, or \$5.68 per ton, the yield was \$80,558, or \$5.05 per ton. The gross earning was \$81,034, and the net operating profit \$14,848. The operating cost of \$4.12 per ton includes a depreciation charge of 27c. On November 30 the company had cash on hand of \$107,566.15. A crusher, trommel, and conveyor are to be installed in the 451 cross-cut to handle the ore above the 450-ft. level from the foot-wall section. This machinery, it is reported, is all at the mine and will be in operation within the next two months.

M. J. Jordan, one of the owners of the first claim in the Antelope district, stated that the first carload of ore from the district, recently shipped from his property, yielded an average of \$230 per ton, as shown by the returns of the Western Ore Purchasing Company.

HUMBOLDT COUNTY

It is reported that the dispute between the Mammoth National company and J. L. Workman, which has retarded development of the properties concerned, has been adjusted, and that operation will be resumed. The details of the agreement have not been made public.

The Humboldt Con. Mines Co.'s adit is now in 285 ft., and it is believed that it will intersect the vein by next month. The company owns eight claims four miles from Rye Patch.

LYON COUNTY

S. Delzappo and P. Maionchi, lessees of the Wild Horse mine, Mt. Grant district, have discovered a 4-ft. vein of ore running \$15 to \$20 per ton, says a report from Yerington. The property is developed by a shaft 135 ft. deep.

NYE COUNTY

(Special Correspondence.)—It is stated that Bullfrog West Extension company will be reorganized and operations resumed at the mine. William Teague, W. T. Coch-

ran, and J. Sheppard, Jr., of Fresno, together with Thomas K. Code, of Rhyolite, have taken over the property and acquired the Eclipse mill. A first payment on the mill is said to have been made. The capacity of the plant will probably be increased. It is understood a large quantity of good-grade ore is on the dumps and exposed in the mine workings. The Poak-Steen-Cieila lease is operating the Lemon mill on a 3000-ton shipment of ore, said to average about \$22 per ton. The plant is treating 50 tons per day. On the 400-ft. level the lease has proved the orebody for over 75 ft., and it is said to be about 30 ft. wide and to assay \$22 per ton. The lease is the principal one operating on the Big Four. The Mineral Hill Consolidated is sacking high-grade ore which is claimed to assay \$240 per ton. The adit is expected to intersect the vein within three or four weeks. A 3-ft. orebody opened on the 165-ft. level of the White Caps is estimated to average \$100 to \$140 per ton. The new machinery being installed at the War Eagle mill will increase its capacity to 85 tons per day. With the completion of the Associated plant and additions to the War Eagle, the capacity of Manhattan's custom mills will be 200 tons per day. The development of a large vein on the 800-ft. level of the MacNamara is about to be started. The mill is running on ore averaging around \$12 per ton, with a considerable quantity available. It is reported the Tonopah Extension company plans to sink a 3-compartment shaft during the coming summer. It will be about 1200 ft. west of the present shaft. A new shoot of rich ore has been opened on the 400-ft. level.

Tonopah, January 27.

J. A. Thatcher, of Pueblo, Colorado, in reply to a rumor that he and Mahon D. Thatcher had secured an option on the Manhattan Big Four property, recently stated that he was not interested in getting control of the mine. Other rumors concerning the property were to the effect that some of the lessees were unable to cope with the heavy flow of water, and that the parent company would not help the lessees, but would itself attempt development by caving.

(Special Correspondence.)—Placer mining in the main gulch is progressing steadily, the cold weather having little effect on activities. 'Dry Wash' Wilson, the largest operator, has a force of 30 men employed, and several companies are shipping bullion. Several new leases have been recently taken and increased activity will set in with spring.

Manhattan, January 26.

STOREY COUNTY

The Ophir mine last week produced 327 tons of ore, averaging \$25.46 per ton, the lowest figure for some time. The Mexican mill crushed 478 tons of ore averaging \$12.35 per ton. The Crown Point produced ore valued at \$3000, including shipments of 335 tons from the Yellow Jacket shaft to the Gloryhole and 556 tons to the mill, which resumed operation January 25. The repairs to the east half of the mill have been completed.

At the recent annual meeting of the Crown Point company the board of directors was reelected, with G. S. Sturges as president and manager for the company. The mine produced \$67,778 during the year. The company ended the period practically free from debt, it is reported. During the year two 10c. assessments were levied.

The Comstock Pumping Association has the situation well in hand at both the C. & C. and Ward shafts. A flow of water has been developed on the 2450-ft. level of the Ward in what is known as the Combination connecting drift. The water is handled adequately by the pumps on the 2475-ft. level. The object of the drift is to effect better drainage and ventilation through connecting the Ward and Combination shafts.

WHITE PINE COUNTY

The Steptoe Valley M. & S. Co. is planning to add two units to the concentrator at McGill, preparatory to handling the low-grade ore from the Gironx property, says a recent report. The addition will cost between \$80,000 and \$100,000. The annual meeting of the Gironx Con.

Mines Co. has been called for February 6 at Duluth, Minnesota. Whether or not the McGill concentrator will be used or the concentrator at Kimberley will be enlarged will be determined then.

The Eastern M. Co. will equip its property with an air-compressor and drills, says a report from Ely. The force of men in the adit will be enlarged. W. A. Douglas is in charge for the company, which was organized recently to take over the property, formerly known as the Nuckolls-Borchert group. The property is in the Cocomongo district.

NEW MEXICO

SANTA FE COUNTY

The Santa Fe Gold & Copper M. Co. on January 1 had in the treasury \$27,984, as compared with \$38,832 on the same date last year. The stockholders at their annual meeting in Jersey City reelected directors. Both smelter and mine have been idle during the year, as it was not deemed advisable to start operation on account of the high cost of coke and supplies. Ore reserves are ample for four years. Expenses during the past year amounted to \$13,280.

SOCORRO COUNTY

(Special Correspondence.)—The Ernestine M. Co.'s new power-plant is now in full commission, using fuel oil.

OREGON.

The mill treated 740 tons of ore the past week, producing 45 sacks of high-grade concentrate. Development work on the third level of the Deadwood Mines is showing good results. During the week 45 ft. of driving was done. The mill handled 250 tons of ore the past 7 days, with a concentrate product of 15 tons. Practically all the machinery for the Socorro Mines' new power-plant, some single parts of which weighed over seven tons, has been delivered and is being set up as rapidly as possible. No date has been announced for the operation of the equipment. The mill is handling upward of 200 tons of ore per day.

Work continues steadily in The Oaks Co.'s main drainage and transportation adit. Development on the Pacific is showing good results, ore having been found in the adit, the face of which is now in 210 ft. A hoist for the South shaft is in transit and is expected to be in commission early in February. On account of the recent extremely cold weather, the Treasure M. & R. Co.'s mine has had a shortage of power generated by water, and hand-steel has been employed in ore breaking. The mill is running up to capacity again since the condition of the road permitted regular hauling of ore from the mine, a distance of about three miles.

Mogollon, January 26.

OREGON

BAKER COUNTY

Production at the North Pole mine, according to a recent announcement, is to be maintained at the rate of 10

tons per day. The ore is shipped to the Oregon-Idaho Investment Co. at Baker, where it is sampled and sent to the Tacoma smelter.

CROOK COUNTY

A rush is on toward the Deschutes river near Lower Bridge owing to the discovery of gold-bearing sand there. Samples sent to Portland by M. Robinson, of Redmond, assayed \$1.50 to \$18 per ton. More than one hundred claims have been staked.

JOSEPHINE COUNTY

The Oriole G. M. Co. is planning to build a 50-ton mill as soon as the roads are passable, says a report from Grants Pass, where the annual meeting of the corporation recently was held. The mill is to cost, it is said, about \$70,000. O. S. Blanchard, Grants Pass, is secretary of the company.

UTAH

BEAVER COUNTY

Willard Peterson and J. H. Erickson, lessees of the Golden Reef property, near Frisco, plan to sink the main shaft to a depth of about 400 ft. and to drive an adit to tap the upper vein of the property. They last December secured a three-year lease on the mine from the Golden Reef M. Co. under which they agreed to do the annual assessment work and to pay a royalty of 15% of the net value of the ore produced.

JUAB COUNTY

A newspaper report states that the J. C. S. M. Co. has voted to sell its three claims at the mouth of Rock canyon to the Hiawatha M. Co., a Knight company, for 17,500 shares of the latter corporation's stock.

SALT LAKE COUNTY

Ore assaying as high as 245 oz. silver per ton has been discovered in the winze below the 900-ft. level of the Utah Mines Coalition property, in the Big Cottonwood district, according to a recent press report. Valuable ore also is reported to have been found in the raise, about 50 ft. above the 800-ft. or adit level.

SUMMIT COUNTY

There has been little activity at the Daly West mine and mill recently, owing to the burning of the loading station on January 20. The platform has been replaced and a new building is being erected.

F. V. Bodfish, general manager of the American Flag mine at Park City, recently stated that the prospecting work carried on by the company has had encouraging results. The prospecting is being done to develop sufficient ore to justify the erection of a large mill. No ore has been shipped since last April, although from the preceding November to the time shipping was stopped about 1000 tons of \$22 ore was sent to the A. S. & R. Company.

Shipments from the Park City district for last week are reported as follows: Silver King, 1,400,760 tons; Daly-Judge, 960,000; New York, 165,000; total, 2,525,760 tons of ore.

WASHINGTON

CHELAN COUNTY

The Wenatchee M. & M. Co., operating at Entiat, announces a dividend of 1 $\frac{1}{2}$ ¢ per share. This is the second monthly payment.

FERRY COUNTY

The Quilp Mining Co., operating at Republic, has paid its fifth dividend of 1¢ per share, or \$15,000, bringing the total paid in dividends to \$67,500. The company's income is from royalties on ore shipments made by the Imperator-Quilp company, which has a lease and bond on the property. J. L. Harper is general manager for the operating company.

CANADA

BRITISH COLUMBIA

The zinc smelter to treat the Lucky Jim ore, in the Sloan

district, probably will be situated at Medicine Hat, according to a recent report, as gas and clay needed for smelting are available there.

The International Lead & Iron Co. will erect two blast-furnaces, with a capacity of 500 tons per day for the manufacture of pig iron and cast-iron pipe within ten miles of Spokane, Washington, this year, according to H. H. Shallenberger. The company owns 800 acres fifteen miles south of Salmon, north of the boundary and nine miles from a railroad, but the extension of the Idaho & Washington Northern railroad from Trail to the boundary line will afford a through rail route to Spokane. The mining company's properties and reduction plant will amount to more than \$2,000,000. Mr. Shallenberger announces that work on the furnaces will begin within 90 days. The ore will be mined with steam-shovels.

The Kootenai Bonanza Mines, Ltd., recently incorporated with a capital stock of \$3,000,000, has secured 40 claims on Toad mountain, near Nelson. Among the properties is the Silver King mine. The company plans to build a plant for treating its ore. The directors are R. S. Lennie, A. E. Rand, and J. A. Hendry, of Vancouver, and W. F. Page and A. C. Burdick, of Victoria.

ONTARIO

The Dome Mines Co. has just made its first report covering the year ended November 30, 1911, showing gross income of \$1,313,483, of which \$999,970 was derived from the sale of 99,997 shares of stock at par; \$309,236 insurance recoveries, and \$4277 from the sale of gold. The property is now being equipped in the most permanent and substantial manner. The mill, which is now nearly completed, consists of 40 stamps, with tube-mills and cyanide equipment, and is expected to handle from 350 to 400 tons per day. Operation is to begin during the latter part of February.

The North Dome-Temiskaming fight is still on, and a contest for proxies is under way. The next meeting is scheduled to be held at Toronto on February 24, when a further effort will be made to oust the Burr Cartwright management. There is a recent story to the effect that the Nipissing interests would step in as peacemakers and by acquiring control of the Temiskaming take over both that company and the North Dome. The Temiskaming management brought down the wrath of the shareholders upon its head by passing the 3% quarterly dividend and diverting the funds for the purchase of the North Dome on a basis of \$229,000 for a controlling interest. The Nipissing rumor probably grows out of the fact that E. P. Earle, of the Nipissing directorate and the president of the company, has recently acquired an option on the Tommy Burns property in Porcupine, which allows some development work to be done and carries a right to acquire control if the showing is satisfactory.

Electrical equipment, including a 100-hp. motor, has been ordered for the Moneta mine, Porcupine district. Material for 16 cyanide vats for the Hollinger plant has been ordered also. The Toronto Iron Works has the contract for the cyanide plant.

YUKON

L. B. Burwash, a Government mining engineer, is quoted in the *Dawson News* of January 12 as stating that he saw three pans washed in the new Sixtymile river district which yielded 40c. per pan. He stated that only the shaft 'on discovery' had reached bedrock. When he was there 357 claims had been staked, but the staking had been poorly done and in some places the claims are off the creek.

E. Chesworth, of Steele creek, recently sent a letter, with an affidavit attached, to the *Dawson News* to the effect that there are two distinct channels, one coarse and the other fine gold, on Discovery bench, Fortymile River district. In the coarse-gold channel he states he made \$2 per cu. yd., and that the district will be opened next summer. He closes his letter with an offer to pay a salary and all expenses in addition to a bonus to any "honest geological engineer if he proves this statement is not true."

MEXICO

CHIHUAHUA

The *Chihuahua Enterprise* reports that the state officials have been preparing, through secret agents, to coöperate with the large mining companies to put a stop to 'high-grading.' The principal districts where the officials have made investigations are Cusihiuiriachie, Santa Barbara, Santa Rosalia, and Parral.

The North-Western railroad recently put into effect graduated ore tariffs based on the smelter assay value of the ore shipped. Under the new schedule the charges on first or low-grade ore from Cusihiuiriachie district to Chihuahua is \$2.40 per ton, for second-grade ore \$3.50 per ton, and for the higher grades proportionate amounts, up to \$100 per ton. The plan was copied from that of the Canadian Pacific railroad. The North-Western is the first Mexican road to adopt the schedule.

SONORA

The Mina Mexico is planning to substitute auto trucks for burros in the transportation of supplies, and to that end is improving the road to the property.

Among the Copper Mines

Sinking at the Wolverine shaft in the Lake district, on the Osceola vein, has reached a depth of about 340 ft. It has been decided to continue sinking an additional 100 ft. or so before commencing driving.

According to cable advices received last week, the second unit of the Braden concentrator has been placed in commission. When its concentrator is completed the company is expected to produce at the rate of about 35,000,000 lb. of copper per year.

Tennessee Copper has declared a dividend of \$1.50 per share, payable February 20 to stockholders of record January 31. This is the first dividend declared since January 1911, when a similar amount was paid. During the six years 1906 to 1911, the company has paid a total in dividends of \$9.75, or an average of \$1.62. per share per year.

It is rumored that the Utah Consolidated is considering purchasing the Yampa property. The Yampa ore has an excess of iron, making it valuable for smelting in connection with silicious ore. The Consolidated is shipping about 500 tons per day of 3% copper ore and 75 to 100 tons of high-grade lead ore to the International S. & R. Co. smelter at Tooele.

The rumor that Wolverine was seeking control of Centennial and that the strength of the latter was thus accounted for was quickly dispelled by John Stanton, according to a recent report. It is very doubtful if anyone took the story seriously, at least among those familiar with the relations between these companies. The tendency at Centennial is toward improvement, meanwhile production is rather secondary to development work, which is being pushed vigorously to the end of increased shipments at the earliest possible date. That current operations are showing a profit is due largely to the advance in price of the metal.

The current week witnessed the initial dividend declaration of the Greene-Cananea, being 25c. per share, payable March 1 to stock of record February 10. Accompanying the declaration was an estimate of the results for 1911, in which production is placed at 45,247,218 lb., and costs at 10½c. per pound, the latter including an item of 2½c. per pound for new construction. Net profits are placed at \$1,140,000, equal to about 46c. per share. This points to an average selling price of about 12½c. For 1910 this company reported a production of 45,680,145 lb. of copper, and costs of 11.5c. per pound, while for the year previous the figures of production reached 44,547,689 lb. and the costs 11.9 cents.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

GEORGE F. KUNZ is in San Francisco.

A. C. VEATCH was in San Francisco this week.

V. R. GARFAS is at Stanford University temporarily.

SUMNER S. SMITH has gone to Chitina from Cordova, Alaska.

M. K. RODGERS has returned from Mexico and gone to Seattle.

RALPH ARNOLD will return from New York to Los Angeles tomorrow.

FREDERICK G. CLAPP is in the Gulf Coast oilfields of Louisiana and Texas.

Z. CUSHING was in San Francisco this week and has gone to Chihuahua, Mexico.

HENRY GANNETT, who has been in Mexico for some weeks, has gone to Washington.

J. C. WEIR has been in Nevada for some time, and has returned to San Francisco.

FRED T. WILLIAMS has been in the northern part of Utah on professional business.

J. W. MALCOLMSON passed through San Francisco from Sonora, Mexico, to Winnemucca, Nevada.

M. F. SIMONDS, of Simonds & Burns, is on his way to the Rawley mine, Bonanza, Saguache county, Colorado.

HOWARD R. STEWART was in Barbados and Trinidad recently and expects to be in San Francisco during the month.

E. A. JULIAN, general manager for the Nevada Hills Mining Co., is ill at the Adler sanitarium in San Francisco.

GEORGE A. LAIRD, GEORGE W. RITER, and MILNOR ROBERTS have been elected members of the Mining and Metallurgical Society of America.

E. V. BRAY has left San Francisco to take charge of the all-sliding plant of the Exploratie en Exploitatie Maatschappij, Dutch East Indies.

GERALD M. BROWNE, of Pearce, Kingston & Browne, London, has completed examination of the Lucky Tiger mine in Sonora, Mexico, for London clients.

FRANK H. PROBERT is in New York in consultation with officers of the Ray Central and Proprietary Mines companies. He expects to return to Los Angeles on February 10.

N. F. DRAKE will lecture before the Mining Association, University of California, on the coalfields and coal-mining in China, February 8, at 8 p.m., Room 200, Mining building, Berkeley. The public is cordially invited to attend.

W. L. BOWRON has resigned as superintendent for the Gold Hill & Iowa Mines Co., at Quartzburg, Idaho, and will make a short study of mining and milling methods in and around Bingham, and then go to California for a vacation.

PHILIP ARGALL, H. F. BAIN, F. W. BRADLEY, H. M. CHANCE, F. L. GARRISON, C. W. GOODALE, J. F. KEMP, T. H. LEGGETT, WALDEMAR LINDGREN, S. W. MUDD, H. S. MUNROE, and H. V. WINCHELL have been elected to the Council of the Mining and Metallurgical Society of America, and J. PARKE CHANNING, J. R. FINLAY, W. R. INGALLS, H. M. CHANCE, and H. S. MUNROE constitute the Executive Committee.

GRACE M. BUCKLEY, widow of E. R. Buckley, died January 24 at Wilmette, Illinois, of pneumonia, following her husband, whose death from the same disease January 19 was announced last week.

CHARLES L. HILL, one of the pioneer mine operators of Colorado, died at Santa Maria, California, January 20, at the age of 83. Mr. Hill mined at various times in Gilpin, Lake, Park, and other counties in Colorado, and did much to develop the mineral resources of that state.

LOCAL METAL PRICES

San Francisco February 1.

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore-producer could expect to realize. Ore contracts usually call for settlements on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

Antimony	11-11½c	Quicksilver (flask)	43.50
Electrolytic Copper	15-16½c	Tin	47-48½c
Pig Lead	4.50-5.45c	Spelter	7½-8½c
Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50			

METAL PRICES

(By wire from New York.)

Average daily prices in cents per pound, based on whole-sale transactions, standard brands.

Date.	Electrolytic Copper.	Lead.	Spelter.	Silver, per oz.
Jan. 25	14.05	4.45	6.45	57½
" 26	13.92	4.45	6.45	57½
" 27	13.85	4.45	6.45	57½
" 28	Sunday.	No market.		
" 29	13.85	4.45	6.45	58½
" 30	13.80	4.25	6.45	58½
" 31	13.85	4.25	6.45	58½

SILVER

Below is given the average New York quotation, in cents per ounce, of fine silver for the months indicated:

	1911.	1912.	1911.	1912.
Jan.	54.33	57.64	July	52.57
Feb.	52.23	...	Aug.	52.17
Mch.	52.76	...	Sept.	52.43
Apr.	52.32	...	Oct.	53.37
May	53.31	...	Nov.	55.77
June	53.04	...	Dec.	54.45

LEAD

Lead is quoted ordinarily in cents per pound or dollars per hundred pounds delivered at St. Louis or New York. The difference is normally 15c. per hundred pounds, and any larger or smaller difference is promptly met by sales. The daily price in New York is published each week in this column. Below are the average quotations by months:

	1911.	1912.	1911.	1912.
Jan.	4.49	4.39	July	4.50
Feb.	4.44	...	Aug.	4.50
Mch.	4.39	...	Sept.	4.48
Apr.	4.41	...	Oct.	4.27
May	4.37	...	Nov.	4.30
June	4.34	...	Dec.	4.45

ZINC

Zinc is quoted as spelter, standard Western brands, and based upon St. Louis or New York delivery. While New York quotations, as a matter of convenience, are commonly used, relatively little spelter actually goes to or comes from New York. The bulk is shipped direct from the plants in the Mississippi Valley to manufacturers, due allowance being made for freight. New York daily quotations are published in this column each week. Below are given averages by months:

	1911.	1912.	1911.	1912.
Jan.	5.47	6.44	July	5.70
Feb.	5.52	...	Aug.	5.95
Mch.	5.56	...	Sept.	5.86
Apr.	5.40	...	Oct.	6.10
May	5.35	...	Nov.	6.38
June	5.50	...	Dec.	6.30

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the car-load can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average monthly quotations in dollars per flask of 75 lb., are given below:

	1911.	1912.	1911.	1912.
Jan.	44.60	43.50	July	48.00
Feb.	48.40	...	Aug.	50.00
Mch.	52.50	...	Sept.	47.50
Apr.	50.90	...	Oct.	46.12
May	46.50	...	Nov.	45.50
June	46.50	...	Dec.	44.50

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations, averaging about 5c. per lb. higher than New York, are quoted weekly in this column. Below are given average monthly New York quotations in cents per pound:

	1911.	1912.		1911.	1912.
Jan.	41.25	42.25	July	42.40
Feb.	41.61	Aug.	43.32
Mch.	40.16	Sept.	39.75
Apr.	42.18	Oct.	41.18
May	43.11	Nov.	43.12
June	44.61	Dec.	45.00

COPPER

Daily quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Below are average monthly quotations in cents per pound:

	1911.	1912.		1911.	1912.
Jan.	12.39	13.92	July	12.47
Feb.	12.59	Aug.	12.41
Mch.	12.14	Sept.	12.20
Apr.	12.02	Oct.	12.19
May	11.99	Nov.	12.61
June	12.39	Dec.	13.89

COPPER SUPPLIES

Figures showing the visible supply of copper at the beginning of each month are now widely available. Below are given the amounts, in pounds, known to be available at the first of each of certain months.

	U. S.	Foreign.	World.
January 1909.....	122,357,266	124,716,480	247,073,746

Tungsten ore, 65%, $\frac{1}{2}$ ton	455.00	500.00
Vanadium ore, 15%, $\frac{1}{2}$ ton	150.00	180.00
Wolfamite (see tungsten ore).		
Zinc ore, 50% up, $\frac{1}{2}$ ton	*15.00	20.00

The Westinghouse Equalizer Hoist

The Calumet & Arizona Mining Co. has recently completed an elaborate set of tests on the electric hoisting system which has been in operation since the latter part of September 1909 at its mine in Bisbee, Arizona. The equipment has been proved satisfactory in every respect and particularly in the ease with which it is handled and the complete control which the operator has. Tests have shown that, even under severe operating conditions where the hoist is running a great portion of the time, the average input to the system over a day's run will not exceed more than about 20 or 25% of the maximum load, and that the rate of input is practically constant.

The increased use of long-distance, high-tension transmission lines has brought electric power to even the more remote mining districts. With small hoists, it has been found satisfactory to use alternating-current induction motors directly applied, but where heavy loads are to be handled, and at high speed, the peak due to the acceleration of the rapidly moving parts is always greatly in excess of the average requirements of the hoist. If the current is obtained from a line also carrying a lighting load, the resulting fluctuations of voltage prove most objectionable. In most cases the hoist is at the end of a long transmission line, and so an excessive amount of copper must be used to prevent drop in the voltage during maximum demand. The result is that the line must be equipped for peak instead of average load and at a greatly increased expense.

The above undesirable conditions have been overcome by the Westinghouse equalizer system hoisting plant, the essentials of which are diagrammatically shown below. It

C. & A. EQUALIZER HOISTING SYSTEM.

consists of a direct-current motor, direct-connected to the hoist drum, and a fly-wheel motor-generator set which includes a direct-current generator, a laminated fly-wheel, an alternating-current induction motor, and an exciter. The equipment also includes a reversing controller for the generator field, a speed regulator, a series transformer, and a switchboard. The hoist proper was built by the Denver Engineering Works, and has a normal duty of 6000 lb. unbalanced load. Its speed is 1000 ft. per minute. The ultimate depth of the shaft is to be 1200 ft. The armature of the generator and the hoist motor are electrically connected direct. The field of each machine is excited separately, constant full field being maintained in the motor. The hoist is started by gradually increasing the field of the generator and so delivering a proportional voltage to the hoist motor. When the load on the alternating-current motor reaches a certain point, resistance is automatically applied to its secondary circuit, reducing the speed of the set, and the energy stored in the fly-wheel is used to overcome the peak of the hoisting cycle. Thus there is a minimum use of current. The hoist is stopped by gradually weakening the generator field and thus allowing all excess in the descending cage, the rotating hoist motor, and the drums, to be returned to the fly-wheel through the generator, which momentarily acts as a motor, receiving energy from

the hoist motor, which for the moment acts as a generator.

The over-all efficiencies of hoists of this type are generally from 50 to 60% when operated under normal operating conditions. Because of the ease of control and the general characteristics of the set, it is a simple matter to devise reliable safety appliances which do not depend on mechanical brakes. Such devices have been put in practice in Germany, where the Government allows men to be hoisted at a speed of 2500 ft. per minute with this type of hoist, whereas with steam-hoists provided with the best available safety devices, the maximum speed allowed is but 1200 ft. per minute. The success with which this Westinghouse system has operated in this country and abroad has been such that a great increase in its use is anticipated as it becomes known. The first cost is somewhat greater than a small motor hoist with rheostat control, but the reduction of power-cost due to the equalization of the load is so great that the initial expenditure becomes a secondary matter, especially when power is purchased on a maximum demand system.

California Mineral Statistics

The recently appointed State Mineralogist of California, W. H. Storrs, is now collecting data relative to mineral production for 1911, as required by law. The result of this work, published in an annual report, helps greatly in advancing the varied mineral interests in the state. The greater part of the information required is obtained by corresponding with the owners and operators of mineral property. Those who have received inquiry blanks from the State Mining Bureau regarding the output and progress of work in the year 1911 are urged to answer them at once, and any who have only recently engaged in business, or who for any other reason are not on the lists of the State Mining Bureau, will be doing a public service by sending to the Statistician, State Mining Bureau, Ferry building, San Francisco, California, their names and addresses, together with a statement of the amount and value of the minerals they may have produced in 1911, or are now developing. The State Mining Bureau should not be confused with either the U. S. Geological Survey, or the Federal Bureau of Mines.

Commercial Paragraphs

R. J. CHAPMAN, who has been general manager for the Fowler Utilities Co., Fowler, Indiana, has resigned to become associated with J. W. Swaren in San Francisco.

RALPH ARNOLD announces the removal of his offices from the Herman W. Hellman building to suite 917-932 Union Oil building, Seventh and Spring streets, Los Angeles, California.

The ORENSTEIN-ARTHUR KOPPEL Co. has moved its Pacific Coast office from the Chronicle building to the Rialto building, San Francisco. The management of the company is now in the hands of D. W. Dodge and Arthur A. Prausnitz.

MEESE & GOTTFRIED Co., San Francisco, is distributing an attractive combination blotter and calendar, the latter being available for ten years by means of dial arrangement. It is in keeping with the excellent literature of this company.

As an appreciation of the hospitality accorded by THE LUNKENHEIMER Co. to the delegates attending the last convention of the National Association of Stationary Engineers, a testimonial has been presented to the Lunkenheimer Co. by that organization.

THE DETROIT TOOL Co. of Detroit, Mich., has opened a branch office at 578 Monadnock building, San Francisco. This company has placed on the market a tool that combines on a single base a rotary-blower forge, an anvil, vise, pipe vise, emery wheel, and drill press. Such a device is especially valuable for shops that are isolated, and, as the outfit weighs less than 200 lb., it can be lowered into a mine and moved about easily. An attractive booklet will be sent on request.

PRELIMINARY estimates of the January production from the Goldfield Consolidated mines indicate a total for the month of 28,870 tons, with a gross value recovered of \$683,000. The operating expense was \$220,000, leaving a realization for the month of \$463,000. In January 1911 the gross production was \$798,177.

NOMINATION of Mr. J. F. Kemp for the presidency of the American Institute of Mining Engineers, will meet the enthusiastic support of all members of the Institute. A better choice could not have been made. A list of the official nominations is given on another page. There has been some dissatisfaction in the matter of the secretaryship, but whether this will culminate in a rival ticket remains to be seen. Proxies are being solicited by a committee opposed to the proposed amendments to the constitution, as noted in the Discussion department.

LOS ANGELES mining engineers have taken steps toward the organization of a local technical society. Whether it will be affiliated with one of the national organizations is uncertain. Certain difficulties that have arisen in practice in connection with the conduct of local sections of the Mining and Metallurgical Society have caused the Los Angeles engineers to raise questions in advance of application for affiliation with the American Institute of Mining Engineers which had been proposed. Details are given elsewhere.

TECHNICAL societies for students are an excellent feature of many American engineering schools. One phase of this work that has been especially well developed by the Mining Association of the University of California, is the holding of meetings at which addresses are delivered by engineers in active practice. Such informal talks serve the useful purpose of keeping engineers and students in touch and give the latter glimpses of the every-day problems they must prepare to meet. We have published several of these addresses and have the pleasure of presenting another this week, this time by Mr. S. E. Bretherton, whose experience in copper smelting gives especial weight to his words.

GEOLOGISTS are now in high favor and their work secures them larger recognition than at any time in the past. As Mr. A. H. Brooks suggests, this recognition brings with it responsibilities, and if they are to retain their present position they must look well to the character of their work. Deep, fundamental, scientific research must be kept up as a prime means toward further application of their science to the wants of men. It is said that German development of the internal combustion engine, by decreasing dead weight on ships, is about to give the Germans control of the sea. If it prove so, their supremacy will have been fairly won, for, as Mr. Brooks points out, the present lead of Germany in technical progress rests on that leadership in research that all of us freely recognized a quarter of a century ago. America set herself to the task of advancing science and is already reaping a reward in advancement of industry, but it will not do to forget that any impulse shortly runs its

course unless it be renewed. Research is fundamental to progress.

COMSTOCK mines have made and have marred many reputations. It is an open secret that for years operations along the great lode have been conducted with a view mainly to stock market manipulation. Mr. Whitman Symmes, in a series of articles printed in the *Mining and Scientific Press* in October 1908, told the whole sordid tale. His recital attracted the attention of the better element among those in control, and, as a result, he was placed in charge of the more important work under way. Against many difficulties he has struggled to a measure of success, finding real ore and introducing real mining. At the last annual meeting of the companies involved, certain of the old directors who had been receiving commissions on supplies sold to the company, were thrown out of office, though a clean sweep of old directors was not made. Revenge is sweet, and now those who lost office have succeeded in securing the dismissal of Mr. Symmes as a sequel to a disagreement between him and the president of the company. A determined effort, it is said, will be made by Mr. Symmes' friends to re-secure control of the Union Consolidated and Sierra Nevada, and a storm on Bush street impends. We doubt if the game is worth the fight. Something might be made of the Comstock if ownership could be consolidated in the hands of those who cared for mines rather than shares, but the prospect for that does not seem particularly bright. In the meantime Mr. C. E. Julihn, who has been appointed superintendent, is said to be an experienced and capable engineer. Doubtless both Mr. Julihn and Mr. Symmes are well prepared to manage mines, but managing Bush street brokers is decidedly different.

Free Assays and Government Metallurgical Investigations

Several bills have been introduced into Congress this winter providing for modifications in the law governing the Bureau of Mines. We print this week the one introduced by Mr. M. D. Foster, chairman of the House Committee on Mines and Mining, and which, while doubtless not in final form, may be taken as the basis for discussion. The work which the Bureau is now doing has the enthusiastic support of all who have come into contact with its operations. There is a widespread feeling that it has demonstrated its usefulness and has shown that more duties may safely be entrusted to it. There have been numerous suggestions as to proper fields for expansion of its activities. Some of these are good and some decidedly bad. It is time for the real friends of the work to make their influence felt to protect the Bureau, not only from the unfriendly, but from unwise friends. The whole matter was carefully considered first by the various sections of the Mining and Metallurgical Society, and later by the Society itself. As a result, the following general principles that should control any rewriting of the law were formulated:

1. That the scope of the Bureau of Mines should be enlarged so that its function will certainly cover the preservation of health in mining as well as safety.
2. That the functions of the Bureau of Mines should be limited to the elucidation of fundamental principles and the study of questions broadly affecting the mining industry.
3. That governmental encroachment upon private enterprises should be prevented by the organic law.
4. That the engagement in private work by employees of the Bureau of Mines should be prohibited by the organic law.

A bill for an act was drawn embodying these principles

and was submitted to Congress. To those unfamiliar with Congressional practice, to whom it may seem that the law passed in 1910 adequately provides for all these matters, it may be stated that, so long as any one member of either House objects, no appropriation can be made by Congress to a Bureau, except for an object clearly designated by the organic act. If, therefore, there is a question regarding any item in an appropriation bill, any single member can prevent the money being appropriated. It goes without saying also that neither the Director of the Bureau nor the Secretary of the Interior can authorize expenditure for any purpose not specifically authorized by law. It is necessary, therefore, to have definite authority for everything the Bureau is to do. Good work and ability to economically answer needs as they arise, require a law framed on the basis of broad principles. Further limitation is possible at any time through control of appropriations. In modifying the law, however, there should be limitations as well as extensions. For example, we subscribe absolutely to the third and fourth principles enunciated by the Mining and Metallurgical Society which are sound, and the demand for free assay offices, which arises perennially, is ill founded. Such offices would be mischievous rather than useful. Among other proposals is one made by Mr. J. E. Raker of California to establish an experiment station at Auburn, at which assays, analyses, and tests are to be made at nominal charge. We believe thoroughly in experiment stations for engineering as well as for agriculture, but we see no good that can be accomplished by this particular proposal and are in hearty sympathy with the protest already made by the assayers and metallurgists of San Francisco and published on another page. Similar proposals for a Government ore-testing plant in Colorado have been made. We do not believe any such plants are needed. There are plenty of places now where anyone having ores for assay or test can at reasonable charge learn promptly and accurately their value and also their amenability to any known metallurgical process. For the Government to enter this field of work would serve no good purpose and would put it into unfair competition with established private business. Such work is not a study of the "fundamental principles" and of "questions broadly affecting the mining industry." Neither do we agree with those who seem to hold that everything possible toward improvement of metallurgical processes is now being done by private agencies. No one practically familiar with the difficulties faced by the metallurgist in developing a new or unproved process can fail to know of many instances when fundamental scientific data are lacking. This, it should be the province of the Bureau to supply, and that, with proper organization and funds, it can do valuable work along these lines has been abundantly proved by its own work as well as that of other Government bureaus. One who sees in efforts in this direction only the making of "nice jobs for pleasant young men" fails to measure the possibilities of an extremely useful organization. However, if agreement as to principles be effected, concessions as to phrases may be made. The Foster bill, seems to us too broad, and while excellent in general plan and purpose, may well be amended in detail. On the other hand, the bill as phrased by the committee from the Mining and Metallurgical Society seems not to have taken into sufficient account the necessity of opening a road for carrying on such work as the testing of permissible explosives. This is one of the best things that the Bureau of Mines has done. With no police power whatever, it has by mere publicity practically forced the adoption of safe powders in the coal mines. There is no longer any reason why tests of powders should be made free for manufacturers. A moderate fee should be imposed. If this be

turned into the Treasury and not returned to the general funds of the Bureau, there will be ample check on any undue increase in activities along this line. This is but one instance of the sort of work that the Bureau may well do to advantage, and which is, from one point of view, private work. A practicable way, though a closely guarded way, should be left open for the doing of such things. Reason is good here as elsewhere. Neither free assays nor absolute prohibition of metallurgical investigations is desirable.

Baiting the Trusts

One of the greatest deterrents to real progress is often found in the unwise efforts of advocates whose zeal outruns their judgment. Out of this the term 'muck-raking' was born, and through it a movement that is essentially for the public welfare has been brought into a certain amount of disrepute. An instance of this sort is seen in the attacks emanating from various sources which have recently been made upon "the Guggenheims". We have not hesitated in the past to criticize those in control of the American Smelting & Refining Company and the American Smelters Securities Company, both individually and collectively, nor shall we hesitate to do so in the future when, in our judgment, they merit criticism; but we are resolutely opposed to unwarranted and unjustifiable attacks upon these as well as all other corporations. It has recently been charged that the 'Smelter Trust' (in popular terminology) has prevailed upon the United States Government to cease the minting of gold coins and turn over the refining business of the mints to it, and also that it is preparing to unload the Braden Copper Company upon a too confiding public. The first of these charges finds its origin in economies in the Mint service. For the past eight years directors of the Mint have been urging in their reports the uselessness of coining all the gold bullion and foreign coin received at the mints. The amount of gold coin already stored in the vaults of the Treasury is greater than will ever be required, as the only continued demand upon the Treasury is for bars for export. During the first six months of 1904 the total presentation of notes for redemption in gold coin amounted to a little over \$6,500,000, while during the same period over \$60,000,000 in certificates was presented for the purchase of gold in the form of bars. The demand for these is at times so great that it cannot be met, and it has occasionally been necessary to export gold coin. The Royal Mint of Great Britain reported the re-coining of nearly \$10,000,000 of American gold coins in 1910. The British standard of fineness differs slightly from the American, so that these coins were no better than bullion for minting purposes and had the disadvantage of suffering much greater abrasion in shipment. The lack of economy in coining gold for settlement of international balances is evident. We have already expressed our favorable opinion of the policy of discontinuing this unnecessary work and also of the closing of those branch offices of the Mint, which changes in the mineral industry have rendered no longer necessary. That, as an incidental readjustment of this change, much doré bullion which formerly was shipped to the mints for refining, will naturally gravitate to the refineries of the American Smelting & Refining Company and the American Smelters Securities Company is, in our opinion, neither a catastrophe for the individual producer, nor a justification for savage attacks upon those corporations. If the complete cessation of refining by the Mint were contemplated, and if there were no other refineries outside of those possessed by these companies, some alarm would naturally be felt by the individual producers of bullion, but neither

is true. It has been urged that the Government is at a great advantage in the refining of doré bullion because it has not to consider the question of interest, a serious factor in a privately owned refinery. On the other hand, the private refinery is at a considerable advantage, because it operates in connection therewith a lead desilverizing plant and copper refinery (in most cases) and the facility thus afforded for the reworking of by-products, residues, and sweeps, is a notable factor in economy of operation. Gold refining is done at the mints by the Wohlwill process, an excellent method for the production of pure gold, but one not well adapted to the refining of ordinary cyanide bullion, which frequently contains large quantities of base metal, and must either first be inquarted and parted in the usual way or else alloyed with purer gold to bring it within workable limits. It will be seen, therefore, that in some respects the private refiner is at an advantage as compared with the Government. And so long as more than one private refining company is in the field, it does not appear probable that unjust treatment is likely to be meted out to the producer of precious metals as a result of the decrease of Government activities in refining. Specific criticism of improper charges would be more effective than general inveighing against the companies concerned.

The allegations made in regard to the Braden Copper Company, and printed in *Collier's Weekly*, are so vague as almost to defy analysis. The report of Mr. Pope Yeatman to the directors of that company was published in the *Mining and Scientific Press*, December 16, and is readily available to all who are possessed of a sufficient understanding of mining matters to read it intelligently. What degree of success the Braden Copper Company is likely to attain is a matter upon which we have not expressed an opinion. That its technical work is in unusually capable hands is well known, and the main facts as to the property itself are readily available. Each intending investor should study for himself the proposed financing of this as of other properties. Whoever purchases shares in any enterprise, whether it be a corner grocery or a corporation, of which he has no adequate understanding, is speculating, not investing, and should expect a corresponding amount of sympathy if the venture does not prove as profitable as was hoped. If people insist upon buying shares because some one else has done so, rather than because careful study shows them worth buying, they can hardly complain when they fall into the hands of financial sharpers. Development of Chilean industries will, we believe, be good for Chile as well as the rest of the world. At present the whole finances of the country are based practically on the nitre industry, and, profitable as that has proved, it is desirable that they rest on a broader basis. In any country where new industries are being established cheap labor is at first a factor. There is inevitable hardship in the situation, as wants are apt to increase faster than earning power develops, but in making comparisons the fair basis is with what the laborer earned before the new industry came, rather than with what laborers elsewhere in similar but long-established industries are earning. The mines and mills of the Braden Copper Company will give to many Chileans incomes they have never even hoped to have, and developing the copper deposits of our Southern neighbor will diversify the industries of the country in a most desirable manner. We see no evidence of natural depravity in the desire of the management of the company for a continued and ample supply of sober and efficient laborers at a low rate of wage. As labor becomes efficient it will obtain its larger reward in Chile as in North America. It is the way of the world. In the meantime misdirected criticism not only fails of its mark, but serves to discredit intelligent criticism, in this as in every other instance.

Applied Geology—A Review of Progress

By ALFRED H. BROOKS

*The science of geology, generally regarded as having originated in the vague speculations of the cosmogonists hardly two centuries ago, has today become of great practical utility. During the past decade all geologic investigations have shown a marked tendency toward material problems, which is in contrast with the previous decade, when the interests of pure science were much more strongly emphasized. No one will deny that economic, or, as I prefer to call it, applied geology is attracting more and more attention from professional geologists. It is appropriate that the members of this Society should take cognizance of this trend in geologic thought, analyze the conditions which have brought it about, and decide, it may be, whether it makes for the good or the evil of the science.

Before discussing this subject it will be well to attempt a definition of the term 'applied geology.' Some appear to believe that when the geologist emerges from the tunnel's mouth he is at once transplanted into the realm of pure science, and that the miner's candle illuminates only the so-called practical or even commercial problems. I submit that such opinions are not justified. The surveys made as a basis for geologic maps and structure sections, usually classed as belonging to the realm of pure science, often yield results which are the most concrete examples of applied geology. On the other hand, the exhaustive study of

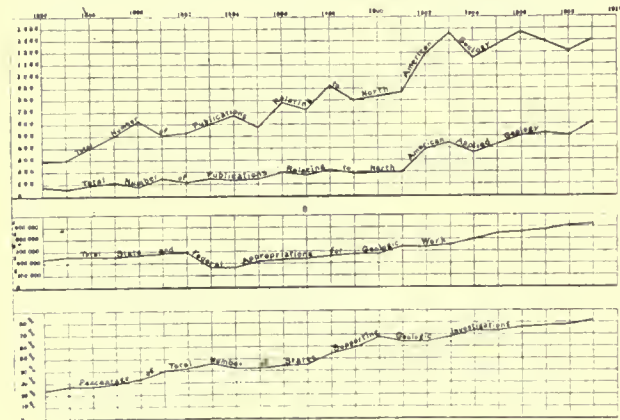

FIG. 1.

mineral deposits is essential to the solution of many fundamental geologic problems. A close analysis will make it evident that the line of demarcation between the fields of pure and applied geology is in a large measure arbitrary. The collection today of a new group of facts or the determination of new principles relating to pure science, may result tomorrow in their application to industrial problems. G. K. Gilbert has recognized two fields of geologic research, the one embracing the study of local problems of stratigraphy and structure, the other, the general problems of geologic philosophy, and has shown that both may yield results of the highest industrial importance. As David Paige has expressed it: "There indeed can be no antagonism between theoretical knowledge and its economic application. The practical expression of a truth can never be divorced from its theoretic conception." If, in spite of what has been said, the two fields of science are to be differentiated, applied geology may be defined as the science which utilizes the methods and principles of pure geology to supply the material needs of man.

While the present tendency of geologic science toward the investigation of problems of everyday life is patent to all, yet it is desirable to express this tendency quantitatively.

*Abstract from a presidential address delivered before the Geological Society of Washington, December 12, 1911. Published by permission of the Director of the United States Geological Survey.

For this purpose, I have determined the percentage of geologic publications issued annually during the last quarter of a century devoted in part or entirely to applied geology. The result of this analysis is graphically presented in the diagram (Fig. 1) in which the one curve represents the total number of publications; another, those classed as bearing upon applied geology. This diagram is based on an actual count, judging by the titles, of the publications included in the annual bibliography of North American geology. It is conceded, of course, that a mere enumeration of titles is, at best, but a crude method, which neither takes into account the extent of the individual publications nor attempts to appraise their value to science. However, I trust it will serve as a rough measure of the activities of North American geologists. On this basis, the diagram clearly records a very rapid increase during the past decade in the ratio of publications dealing with applied geology to the total of geologic literature. The figures show that applied geology was at its lowest ebb in 1890, when only 12%, and at its highest flood in 1909, when 47% of the total publications related to this subject. To consider the percentage of economic papers by decades: In the ten years ending in 1895 the average was 22%; for the following decade, 30%; and for the last five years, 44 per cent.

Another measure of this trend in geology has been obtained by a similar classification of the publications of the United States Geological Survey. The result of this enumeration is shown in a second diagram (Fig. 2). In

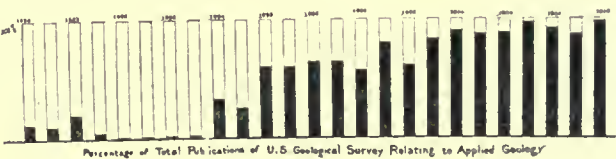

FIG. 2.

this, it will be seen that in 1890 less than 1% of the publications issued by the Federal Survey treated of applied geology, and in 1910 the percentage was 98. Considering it by decades; for the ten years ended in 1895 the average of economic papers was 11% of the total number of publications; in the following decade, 71%; and in the last five years, 92 per cent.

These figures are not to be interpreted as evidence that pure science has not been recognized in these publications of the Federal Survey. I have classed with the applied geology group all publications which treat in any measure of this subject, though many of them deal chiefly with problems of more purely scientific interest. For example, the geologic folios, which include some of the most notable contributions to pure science, are here included in the literature of applied geology. To me it is less surprising that nearly all the recent publications contain some practical deductions than that most of those of twenty years ago omitted all data of this kind.

The marked tendency toward practical problems, as indicated by these figures, is by no means confined to one organization, for it is exhibited in the same degree by state surveys, and is also reflected in the work of the universities. Nor is it limited to this continent, for countries as widely separated geographically and in scientific traditions as South America, Japan, and Germany show similar signs. Everywhere geologic research of practical problems is receiving more and more support, both publicly and privately.

It is pertinent to consider the attitude of the public at large toward this economic tendency. There are undoubtedly those who believe that the direction of scientific work should rest entirely with the investigator and not with the

people. Let them bear in mind that geologic investigations, since they involve heavy expenditures and trespass on private property, can, for the most part be properly carried on only through government agencies, in this differing from such sciences as chemistry, physics, or biology, which can be furthered by private means. If geologic surveys are properly a function of the state, in the last analysis the people must be the final arbiters as to what phase of the science is to be emphasized. In our democracy the citizen has a right to inquire what he, as a member of the body politic, is gaining by expenditures from the public purse.

It is estimated, on the best data available, that during the past quarter century the total grants for geologic work made by state and Federal governments aggregate over \$8,000,000. This may be regarded as evidence of public confidence. More significant to the present discussion is the annual grant of funds during this interval, and this is illustrated by a curve on the same diagram with those showing character of publications (Fig. 1). This curve is in part based on estimates, but these are without doubt sufficiently accurate to indicate that the total annual appropriations of state and Federal governments for geology have been augmented at a rate which proves that they are affected by some other factors than that of increase of population. The annual grant of funds is now more than double that of twenty-five years ago. It is probably safe to interpret this as indicating that the present economic tendency in geology is approved by the people of the United States. The close parallelism between the lines marking the publications relating to applied geology and the annual allotments of public funds for geologic surveys is probably not entirely fortuitous.

Perhaps the best measure of popular confidence in the results of geologic research is the number of different geologic organizations supported by public funds. We are apt to credit the obtaining of government support for this or that research entirely to some individual or organization, forgetting that, until the general public has in a measure been persuaded of its value, all efforts would be useless. Therefore, when we find geologic surveys throughout the country supported by commonwealths having widely different social and industrial conditions, it is fair to presume that the average citizen has acquired the belief that these are attaining results beneficial to the community. The numerical increase of state geologic surveys during the last twenty-five years is illustrated by the curve on the diagram which marks the percentage of total number of states supporting geologic work (Fig. 1). In 1886 24% of the states had geologic surveys; in 1895 the percentage was 42, and in 1910, 80.

This growing public interest is also manifested by the increase in geologic teaching at colleges and universities. I interpret the statistics published by T. C. Hopkins as indicating that in 1886 there were about 220 of the higher institutions of learning in which geology was taught, while in 1894, there were 378. Of these, 51 had geology organized as a separate department. I have been unable to find any more recent data on geologic education, but that it has made great strides in the last seventeen years will be conceded by all. It will also be generally admitted that the teaching of economic geology is receiving constantly greater attention in the colleges and technical schools. More significant evidence of the present status of geology among the people is the fact of the large number of geologists now in private employment. There are many professional geologists who are engaged in consulting practice. Nearly every large mining company and many railways include in their personnel one or more geologists. In a commercial directory of mining experts recently published fully 10% classed themselves as geologists, while an edition of the same directory issued ten years ago included only one who claimed to be a geologist. While at that time, as now, many mining engineers were in fact professional geologists, they did not care to advertise the fact.

All this indicates that applied geology has during the last two decades become a dominant element in our geologic work; also that this tendency toward industrial problems

pervades all geologic investigations, whether under federal, state, or private auspices. Furthermore it has been made evident that this trend is not limited to the North American continent, but is world-wide. It is clear, also, that since emphasis has been laid upon the economic side there has been a marked increase in the support given to geologic work, from which fact may be drawn the logical conclusion that the public endorses this policy. It does not necessarily follow that this dominating practical note in geology has made for the advancement of the science. Before discussing this important question it will be well to trace briefly the origin of geology as an applied science.

It seems to be generally assumed that the application of geology to industry was not attempted until after its development into a more or less complete rational science. It cannot be denied that the application of the principles of a science must await the establishment of those principles through scientific inquiries. It is true, however, that long before geology had developed as a science men observed the geologic phenomena that bore on certain vocations and often correctly interpreted such observations.

The science of applied geology, therefore, had its origin among those who, like the miners, were by vocation brought into intimate contact with natural phenomena. Many of the elementary facts relating to mineral deposits were forced on the attention of the miner, and as the correct interpretation of these facts added to his material welfare, some deductive reasoning was undoubtedly applied. The rudimentary conceptions thus formed were more likely to be correct than those of the early closeted academician, whose science for generations began and ended in pure speculation.

Therefore, to trace the origin of applied geology the oldest archives treating of mining, quarrying, agriculture, engineering, and mineralogy must be searched—a task which has been quite beyond me. And reaching far back of any written record was the traditional lore bearing on geologic phenomena of countless generations of miners and husbandmen. Even the man of the stone age must have subconsciously acquired knowledge of the distribution of the materials which he fashioned into implements of the chase and war. If we are to allow our imagination full scope, we can conceive of some primitive economic geologist who, by finding a deposit of copper and revealing the superiority of the new material for weapons, became the hero of his tribe.

A review of the conditions which brought about the rapid growth of geologic work in this country during the first decades of the nineteenth century cannot fail to consider the political and industrial situation. The war of 1812 had united as one nation the commonwealths which up to that time, in spite of the federation, had strong centrifugal tendencies. During the war with Great Britain, New England had been on the verge of rebellion, while the Trans-Appalachian region was not held to the East by any strong bonds. The country, rent by domestic quarrels and the turmoil of opposing political factions, paid small heed to the problems of industry and commerce.

After the war the people thought less about state rights and more about industrial prosperity. There was no longer a French party or an English party, but men of all political faiths had come to the conclusion that we must work out our own salvation. We had learned to supply our own material needs during the war when English frigates cut off European sources of supply. In short, the nation had found itself and was ready to begin to harvest the resources of the vast territory which the war had settled for all time was to be our own. Our people, while possessing the self-confidence of the pioneer, were facing new problems, and, guided by their scientific instincts, turned to the scientist for help.

In spite of the fact that the war had developed a relatively strongly-centralized federal government, our political theory was still one of state rights. Moreover, the Republicans were in power, with a hopelessly small Federalist minority. It was natural, therefore, that the people, loyal to their political faith, should turn to the commonwealths for aid in developing the new land. This aid for the most part took the form of large grants for public im-

provement of transportation facilities—at first for canals and wagon-roads, later for railways. During the period ended with 1838 the states borrowed sums aggregating \$160,000,000 for purposes of public improvement. Compared with this sum, the expenditures for geologic surveys were small. It is a significant fact, however, that in 1838 a larger percentage of the states supported geologic surveys than in any subsequent year until 1898. This is graphically illustrated in Fig. 3. The upper curve shows the total number of states, and the lower the percentage of total number which supported geologic surveys between 1826 and 1910.

The very rapid increase in state surveys is all the more significant when compared with the status of governmental surveys in Europe. Though much geologic work was done in European countries during the early part of the century, it was not until about the middle, that the governments began organizing systematic surveys. England led by establishing her survey in 1832. Next came surveys of Austria-Hungary and Spain, organized in 1849, of Bavaria in 1851, and France in 1855. Most European countries did not undertake systematic geologic surveys until about 1860, or more than twenty years after our first maximum of state surveys had been reached.

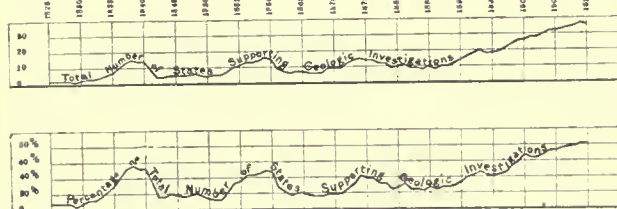

Fig. 3.

As already indicated, the principal influence that has led to this first era of state surveys, as G. P. Merrill has called it, was the widespread interest in scientific investigations, and the great industrial advancement which created a demand for the practical results of such investigations. A good example of the faith the people had in applied geology is seen in the first geological survey of Georgia, which was paid for by land owners of two counties—a condition that has never been repeated until recently in some of the rich mining districts of the West.

Another reason for the large number of state grants for geologic work lay in the general westward movement of population from the Atlantic states. This had a two-fold effect on geologic surveys. First it gave rise to a demand for information about the new lands, and second, it put the older states on their mettle to hold their population. So rapid was the westward movement that the Atlantic states became alarmed for their future. In 1815 and 1816 the legislatures of both North Carolina and Virginia appointed committees to devise means for checking the drain on their population. This was unquestionably the motive in establishing many of the Eastern state surveys, and in directing their activities toward agricultural problems.

Meanwhile the Federal Government had undertaken the investigation of the resources of the unorganized Western territories. The chief purpose seems to have been a classification of the public lands—a work which was to be interrupted for over half a century and then resumed as the proper function of Federal geologists.

According to Merrill¹ the first epoch of state surveys declined even more rapidly than it arose, due largely to the financial crisis of 1837. An era of promotion, inflation, and straining of state credits to their utmost, accompanied by a waste of the borrowed millions and the lack of any sound Federal financial policy, resulted in a money panic, the collapse of many ill-advised enterprises, the repudiation of their public debts by several of the states, and a wide-spread commercial depression. It is no wonder that, under these conditions, geologic surveys were regarded as luxuries

that might well be spared; particularly since these first governmental surveys, it must be admitted, hardly justified themselves from the standpoint of practical results. This fact does not detract from the credit due the pioneer geologists who carried on these surveys under almost insuperable difficulties. They learned much about areal distribution of the larger geologic units, but most of the studies were not detailed enough to yield results of practical value. Moreover, even in that day many geologists were still living in 'flat land'—they considered formations in only the two horizontal dimensions; for while the vertical element was by no means ignored, it was not closely understood.

During the decade following the panic, few states had surveys, and no great progress was made in the science, beyond the publication of results attained in the previous era. Though the contributions to geologic literature by the class of professional geologists—whose appearance was perhaps the most important result of the activity of the previous decade—were not unimportant, yet as a whole both pure and applied science were at a rather low ebb.

The panic was but a temporary check to industries, however. The estimated production of pig iron was 347,000 tons in 1840, and 600,000 in 1850, while the coal production during the same period increased from 2,000,000 to 7,000,000 tons, and the railway mileage from 2812 to 9021. These industrial advancements were accompanied by the rapid settlement of the Middle West, by the beginnings of copper mining in Michigan in 1844, and of iron mining in Michigan and Missouri in 1853, and most important of all, the discovery of gold in California in 1848. All this activity gave a new impetus to geologic work, which is reflected in the revival of interest in state surveys. At this time, too, men began to dream of a transcontinental railway and therefore the Federal Government undertook a more systematic exploration of the western Cordilleran region than had previously been made. The curve of state surveys, as seen in the diagram, continued to rise until the outbreak of the Civil War. In this second epoch of geologic work the states of the Middle West—then the frontier—led. This was but natural, because history has proved geology always appealed more strongly to the pioneer than to any other class of people.

It is difficult to measure the accomplishment of this second period of geologic activity under state and Federal auspices, owing to its abrupt termination by the Civil War, which interrupted many important investigations. One fact stands out clearly: that applied geology was the mainspring of most of the research, and the results indicate that pure science had not been the loser thereby.

The prosperous time following the Civil War in the North and West, with its almost unique industrial advancement, again centred public interest on mineral resources. This caused the Federal Government to resume explorations in the West, which took the form of areal geologic surveys and in some cases detailed study of mineral deposits. Many states undertook similar work, and the curve of geologic surveys arose until the interruption by the panic of 1873.

The results thus attained proved a final justification of geology, not only as an intellectual pursuit, but also as a practical aid to mankind. While the immediate benefits of these investigations were large, they were not so important as the institution of geologic mapping, based on accurate mensuration. Crude as those maps were, compared with the present standards of refinement, they represent the earliest attempt in this country to apply engineering methods to geologic problems. It was very unfortunate that this first epoch of engineering geology, as it might be called, was so soon interrupted and the work practically discontinued for over a decade. The people were, in fact, hardly educated up to an appreciation of its value; moreover, the natural resources that could be readily exploited without the aid of science were so extensive that the time was hardly ripe to make full use of this new geology.

We have seen that the period following the Civil War was especially favorable to the development of applied

¹The extensive use I have made of 'Contributions to the History of American Geology,' by G. P. Merrill, will be evident to all who have read that work.

geology. The same is true of pure science. This, in fact, has been the history of geology in this country—advances in pure science were always in more or less direct proportion to advances made in the applied science.*

It has been shown that, in the early history of the Nation, the genius of the American people was essentially scientific. A deep interest was felt both in the facts and deductions of science, and in the affairs of life deference was paid to the opinion of the investigator. Unfortunately, for reasons which are difficult to fathom, this scientific attitude gradually declined. At the beginning of our national existence we were in close contact with the intellectual life of Europe, which was then essentially scientific. This gave us our first intellectual stimulus and led us to do our full share of the work of advancing both pure and applied science. Then came an interim between the time when we forsook the intellectual standards of the Old World and before we fully established those of our own. Meanwhile, the opening of a continent, with its unbounded resources, was calculated to bring out the characteristic efficiency and self-reliance of the average American. Then gradually developed what may be called the era of the 'practical man'—an era characterized essentially by unscientific thought among the mass of the people. The practical man now became a national fetish, and the people, overlooking the fact that his success was due to energy and opportunity, attributed it rather to the absence of technical and scientific knowledge. Nowhere was this national trait better shown than in the mineral industry, where the era of the 'practical man' cost the Nation untold millions. His distrust of applied science was deep rooted. For a generation every mining community swarmed with these self-styled experts, whose technical and scientific limitations were only exceeded by their blatant self-assertion.

Unfortunately, at this time there also developed between the geologist and the mining engineer an antagonism, which was detrimental to the advance of the science. A school of geology arose which revived to a certain extent the ancient practice of speculation without observation, and regarded itself as moving in a higher intellectual sphere than that of the engineer, who dealt with practical problems. On the other hand, many engineers came to regard all work of the geologist as either visionary or purely speculative.

Since the rise of the modern school of applied geology, which may be said to have begun in the eighties, the antagonism between the engineer and the geologist has gradually disappeared. The geologist has made his results of more value by adopting some of the methods of the engineer, while the engineer no longer hesitates to use geology in his own field. Both professions have been improved by this mutual help, and the geologist has by no means gained the least. The modern mining engineer now recognizes that, even in his own special field, scientific investigations are essential. This is evidenced by the general hearty support given by engineers to the new Federal Bureau of Mines.

It is not necessary to describe in detail the recent progress in applied geology. While most of the countries of the world have taken part, it is a field that the American geologist has made peculiarly his own. Among our important contributions in this field is the geology of mineral oils, presented by M. R. Campbell to this Society last year. In this, as in the survey of coal deposits, stratigraphic and structural geology have almost come to be exact sciences. Equally important to the Nation are the results achieved in underground water investigations. The tectonics of mineral veins now also approaches an exact science; while many of the conclusions on the genesis of orebodies, notably that of secondary enrichment, are among the triumphs of applied geology.

Moreover, the field is being extended. In Germany the work of the geologist is regarded almost as essential to railway or canal location as that of the engineer—a lesson we have only recently learned at Panama. The investigations of soils is now a distinct science, based largely on applied geology. Questions of public health, such as purity

of water and sanitation problems, also in part fall in the domain of the geologist.

A significant phase of the new epoch in applied geology is its contributions to political economy. A striking example of this is the geologic survey of Korea, executed by the Japanese during their war with Russia. It need hardly be said that this was not made for the purpose of advancing geologic knowledge, but solely to gain a scientific valuation of the land which was costing so much blood and treasure. Though the present status of the science does not permit of a quantitative determination of resources which is more than approximate, yet the fact that geologists are being called upon by political economists for assistance indicates how fundamentally the science affects the welfare of the Nation.

This historical survey of applied geology, in which special emphasis has been laid on its progress in this country, seems to point to several conclusions. First, that much of the modern science of geology originated in the field of applied science. It was the striving of mankind to solve problems of material welfare that gave the first impulse to geologic thought. Second, that, as a rule, the science has made most rapid strides at those times when its study was inspired by a desire to achieve some practical end. Whenever geology has become entirely divorced from industry, it has drifted toward pure speculation. The geologists of the past, like those of the present, received much of their inspiration from the fact that they were adding to the material welfare of mankind. Werner, Humboldt, von Buch, de la Beche, were not only trained as mining engineers, but continued for most of their careers to be intimately connected with the mining industry. William Smith was an engineer before he was a geologist, and even Hutton knew from personal experience the value of applying the sciences of agriculture and chemistry. On this continent McClure, Eaton, Rodgers, Owen, Leslie, Logan, Whitney, Orton, Cook, Dawson, and King, with a host of others were all identified with the industrial application of their science. The elder Silliman, in an account of his own training in geology, said: "I learned in the mining districts how and what to observe." The years that Dana spent on explorations may be counted in the field of applied geology. James Hall, for two generations the leader in American geology and the founder of that organization which for three-quarters of a century has preserved the highest scientific ideals, gained his early inspiration in studying practical problems. An enumeration of the leading geologists of the present generation will, I think, show that the larger part have given much attention to the material application of geology.

The recent economic trend of geology is only a counterpart of similar tendencies in most fields of scientific research. The introduction of science into practical affairs is a feature of the present age. It has come about not only because, as the sciences progressed, their results were more directly applicable to material problems, but more specially because of the gradually changing conditions throughout the world. With a sparse population and abundance of natural resources, the need of applied science is never so evident as when the lands become crowded and the more readily accessible resources depleted. The people of a virgin land need pay small heed to exhaustion of soil or destruction of forests, and can carry on shallow mining operations with little recourse to science or technology. It is only when increasing population results in a demand for a greater food supply and makes sanitation important; when the depletion of timber becomes a factor in cost of structures; and the superficial deposits can no longer yield sufficient minerals, that the need of scientific knowledge becomes strongly emphasized. This stage has been reached in most of the civilized countries of the world to a greater or less extent, and the evils of relative overpopulation and depletion of nature's wealth are resulting in an appeal to applied science.

In this respect the present generation has made greater strides than all that preceded. We are now applying science to the affairs of the Nation as never before. The old-fash-

ioned publicist, with his classical education, or at least traditions, is being shouldered out of the way by the man who analyzes the problems of public welfare on scientific principles. The trained investigator is being more and more appealed to in the affairs of the Nation. In this we are following Germany, whose long leadership in pure science has now been overshadowed by her leadership in applied science. We have begun to realize that it is one thing to win prosperity and happiness out of the bounty of a new land, another to gain it by utilizing resources which can only be made available by scientific genius.

Gilbert has said that "pure science is fundamentally the creature and servant of the material needs of mankind." Yet it is not uncommon to find the devotee of pure science assuming that his field is on a higher plane than that of those studying problems which involve the material welfare of the human race. This seems specially true in the field of geology. If a bacteriologist finds a new toxin for a disease germ, a botanist a new food plant, a sanitary engineer a measure for preserving human life, all unite in commending his work. Yet there are not a few geologists, though I believe a constantly decreasing number, who seem to view with suspicion any attempt to make the science of geology more useful. Those who are devoting themselves to economic geology are charged with commercializing the science, as if the applying of its principles to better the conditions of the people were not the highest use to which scientific research could be put. One reason for this attitude is because much which has been masquerading as applied geology is not science at all. The commercial exploitation of natural resources under the cloak of geology is not to be confounded with geologic research, which has for its aims the application of scientific principles to the needs of man.

The geologist who is studying the resources of the public domain to the end that a sound policy may be adopted for their utilization, or he who is gauging the exhaustion of our mineral wealth by studying statistics of production, is doing his share of scientific work no less than he who is engaged in the more pleasing task of evolving new geologic principles. The masters of science have not hesitated to turn their attention to economic problems. Clarence King deserves no less credit for his aid in opening up the West by economic investigations than for his contributions to knowledge on the age of the earth. We think of Major Powell as one of the founders of physiographic geology, but his memory will live rather for employing science to make available the latent fertility of the arid regions of the West. Surely no one will charge King or Powell with commercializing their science.

As I see it, there lies no danger in the present trend toward applied geology, provided our applied geology rests on a broad basis of scientific research. If the spring of pure science is cut off, the stream of applied geology must soon run dry. There is no field of pure geology which will not yield results applicable to questions of material welfare. On the other hand, any given investigation in applied geology may lead to problems of paleontology, petrography, geophysics, or other branches of pure science. In view of the pressing demand for results, we are justified in giving precedence to those fields of investigation which promise the earliest returns of material value. There is, however, grave danger that, carried away by the present furor for practical results, we may lose sight of our scientific ideals. Applied geology can only maintain its present high position of usefulness by continuing the researches which advance the knowledge of basic principles. Future progress in applied geology depends on progress in pure geology.

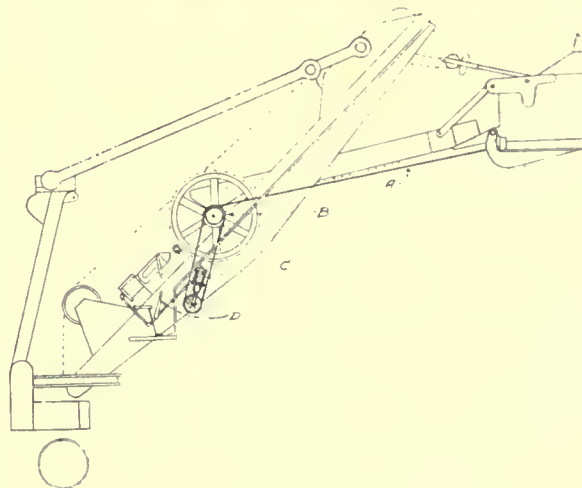

THE iron industry in South Russia shows stock on hand at different works at the end of the first six months of 1911 as follows: Pig iron, 71,244 tons; iron and steel (semi-finished), 34,794 tons; iron and steel (finished), 132,786 tons; in North Russia, pig iron, 65,862 tons; iron and steel (semi-finished), 27,180 tons; iron and steel (finished), 33,534 tons.

Trips for Steam-Shovel Dippers

Soon after the steam-shovels were first set at work in the Culebra cut, at Panama, improvements in the construction of dipper trips began to be made. Owing to the great weight of earth and rock in the 4 and 5-yd. dippers it is at times difficult for the craneman to unlatch the door by the usual hand-pull method, and in the course of a day considerable loss of time results. The first positive action trip, using steam power, was placed by a steam-shovel engineer, Thomas Cnsty, upon his own shovel, but was soon discarded. The device was improved and patented by A. H. Geddes. The latest device, by F. S. Wichman, after having under-

WICHMAN DIPPER TRIP.

SHOVEL BOOM WITH TRIPPING DEVICE.

gone a successful test upon two 95-ton steam-shovels, has been adopted by the Isthmian Canal Commission.

The mechanism of this dipper-door tripper is placed on the boom and has a 1/2-in. wire rope leading to the latch on the dipper door. In order to keep the cable always taut a drum is mounted on the face of the thrust gear, to which one end of the cable is fastened. The drum being the same diameter as the pitch diameter of the rack pinion, the cable is wound or unwound coincident with the travel of the dipper handle. To give the lengthwise pull of the cable, a 6-in. steam cylinder is mounted below the drum. This cylinder has a push piston, the outer end of which is bifurcated to receive a sheave, over which the cable passes on its way to the drum. Steam is admitted to the cylinder when it is desired to trip the dipper door through a "three-way cock" operated by a lever at the craneman's seat.

Operating Costs at the Pittsburg-Silver Peak Mill

A complete description of the mill of the Pittsburg-Silver Peak Gold Mining Co., at Blair, Nevada, was prepared by Henry Hanson, at that time mill superintendent, and published in the *Mining and Scientific Press* soon after the plant was completed.* Detailed statements of mining costs, which for desert conditions are notably low, were furnished within the past year† by Edmund Juessen till recently general manager for the company. Below are given corresponding details covering operating costs in the mill for the year 1911. These are printed through the courtesy of S. J. Kidder, general superintendent, who has immediate charge of the mill.

The general plan of ore treatment is essentially the same as when it was described by Mr. Hanson, though 20 stamps have been added, making the total now 120, and some changes have been made in the handling of solutions and other minor matters. The process involves crushing to 35 mesh with 1050-lb. stamps, 96 drops per minute, with a fall of 6½ to 7½ in. Outside amalgamation is used with a plate area of 12.8 sq. ft. per stamp, and a grade of 1¼ in. per foot. The plate tailing goes to a distributing sump and thence to sizing cones, 4 ft. 3 in. diam., fitted with Merrill hydraulic sizers. Before classification the pulp carries 5 or 6 parts of water to 1 of solid. After classification the sand contains 3 or 4 parts of water and the slime 14 to 16. The leaching-vats are five in number, 36 by 11½ ft. The whole cycle of treatment from charging to charging occupies a little over seven days. The combined overflow from the settling and sizing cones flows to five dewatering tanks. The thickened slime is drawn continuously from a bottom outlet and flows to a sludge storage tank where cyanide and lime are added to make an 0.025% cyanide solution. The pulp is agitated constantly by air and drawn continuously to Merrill filter-presses. Zinc-dust is used for precipitation. The refining process used at the

plant is practically identical with that used at the Homestake mine in South Dakota.

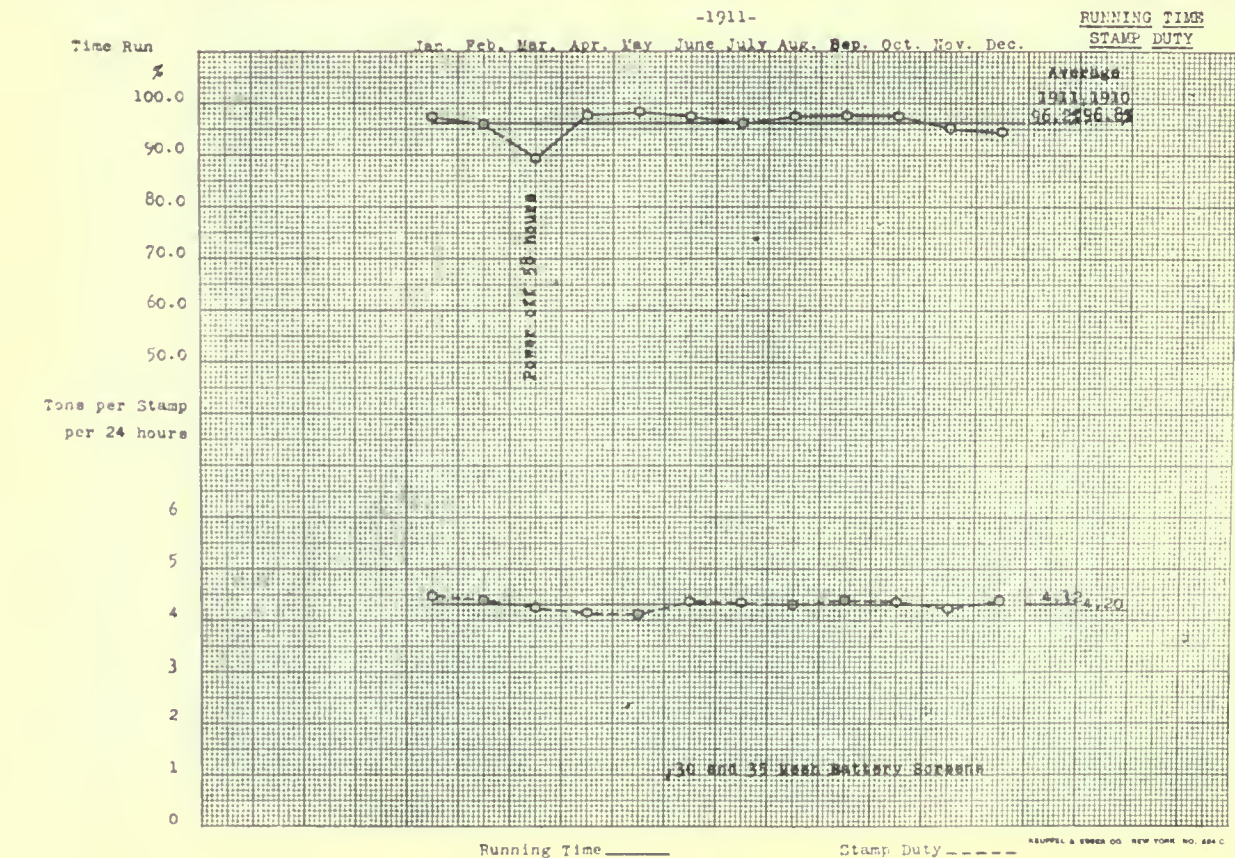

All men employed in mill and cyanide plants work 8 hours. The regular mill-crew consists of 3 men on a shift. In addition to this number are 2 plate-men and 2 repair-men on the day shift, making in all 13 men for the 24-hr. day. In the cyanide department 4 men are employed on each shift, with no extras on the day shift, making the total cyanide crew 12 men for the three shifts. In the refinery 2 men are employed, on the day shift only. Their work consists of cleaning the precipitation-press and carrying on all work connected with the refining of mill and cyanide products. In the assay office, where the assaying for the mine and plant, as well as some custom work, is done, 3 men are employed. The average cost per ton for mining, milling, and all expenses in December 1910 was \$2.60. The average cost per ton for each step in the milling process in 1911 was as follows:

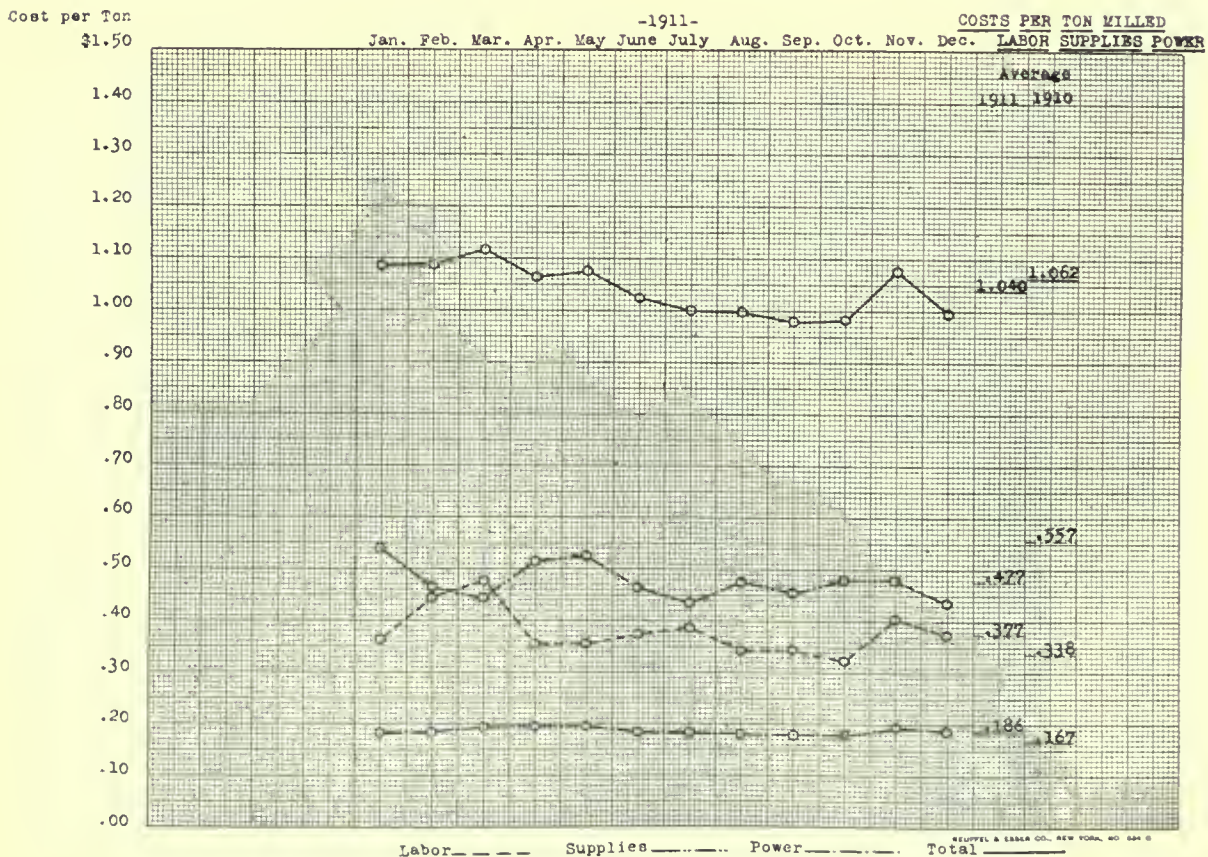

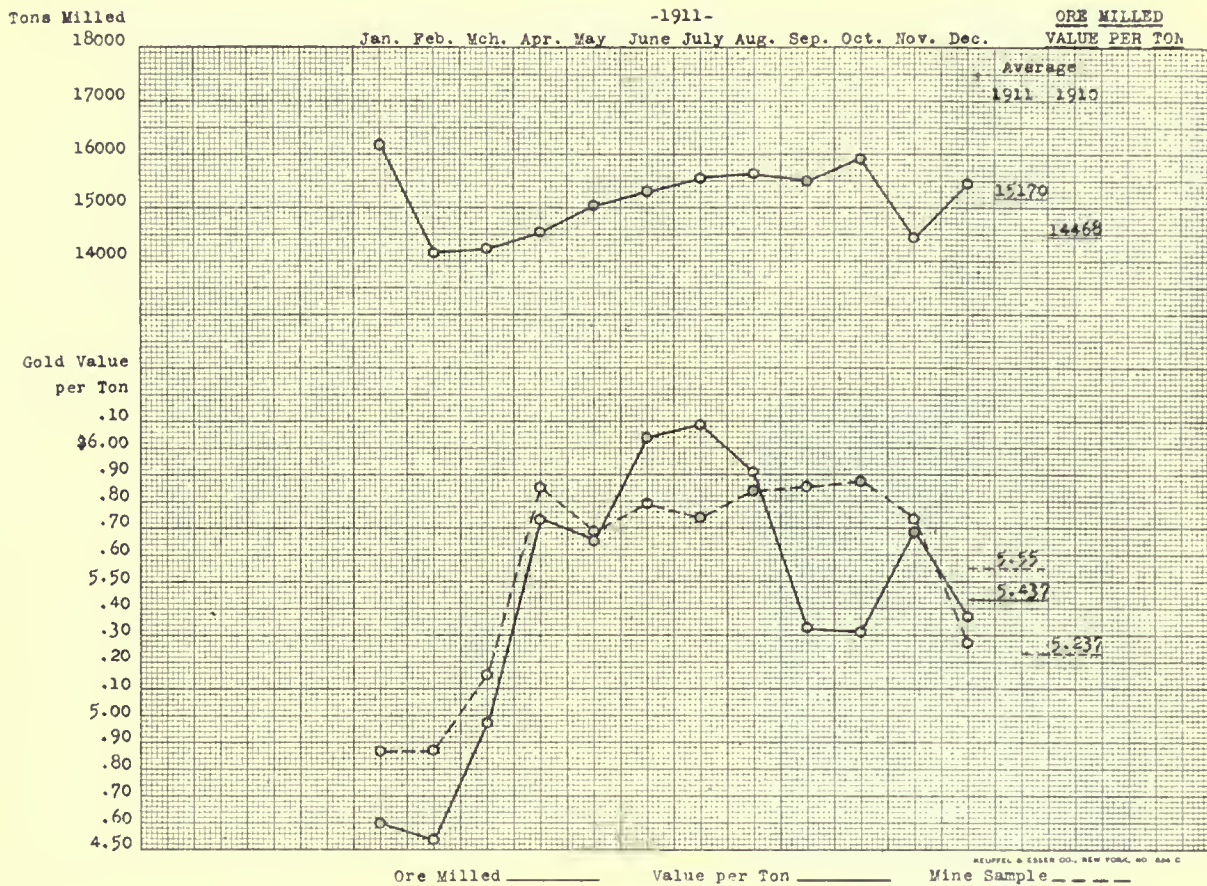

Stamping	\$0.298
Amalgamating	0.047
Neutralizing and settling.....	0.074
Leaching and sluicing.....	0.145
Filter-pressing	0.104
Precipitating	0.036
Refining	0.048
Assaying	0.033
Water service	0.070
Heating	0.007
Superintendent and foremen.....	0.053
<hr/>	
Total direct operating.....	\$0.915
Pro-general	0.079
Suspense account	0.046

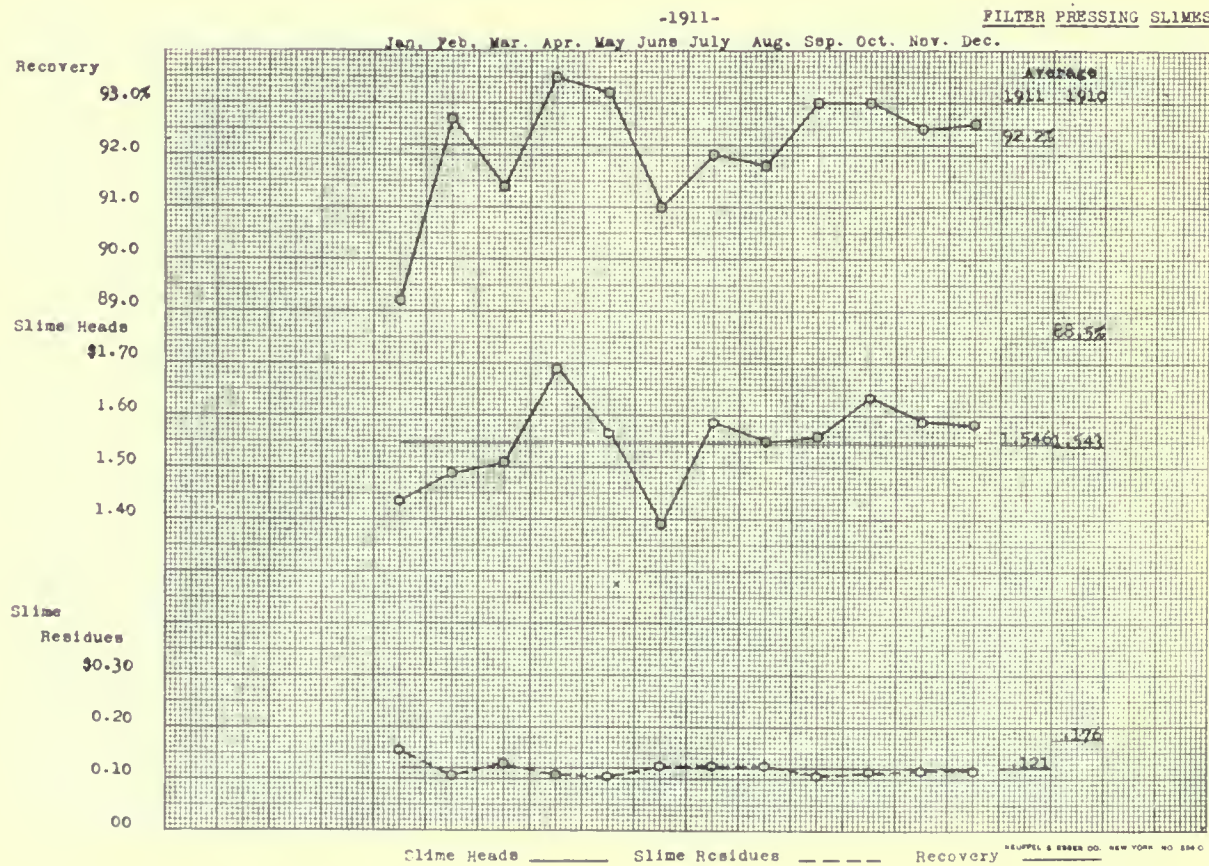

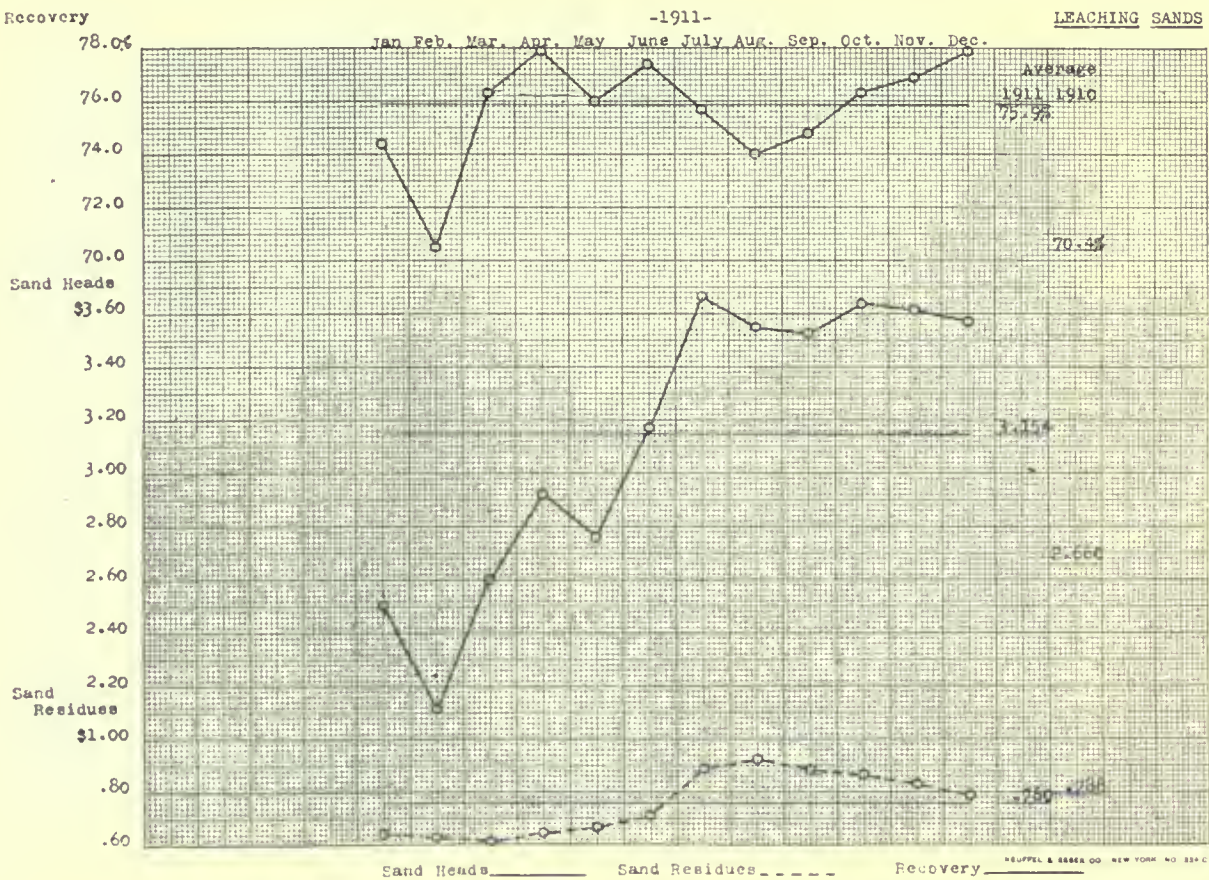

Total operating \$1,040

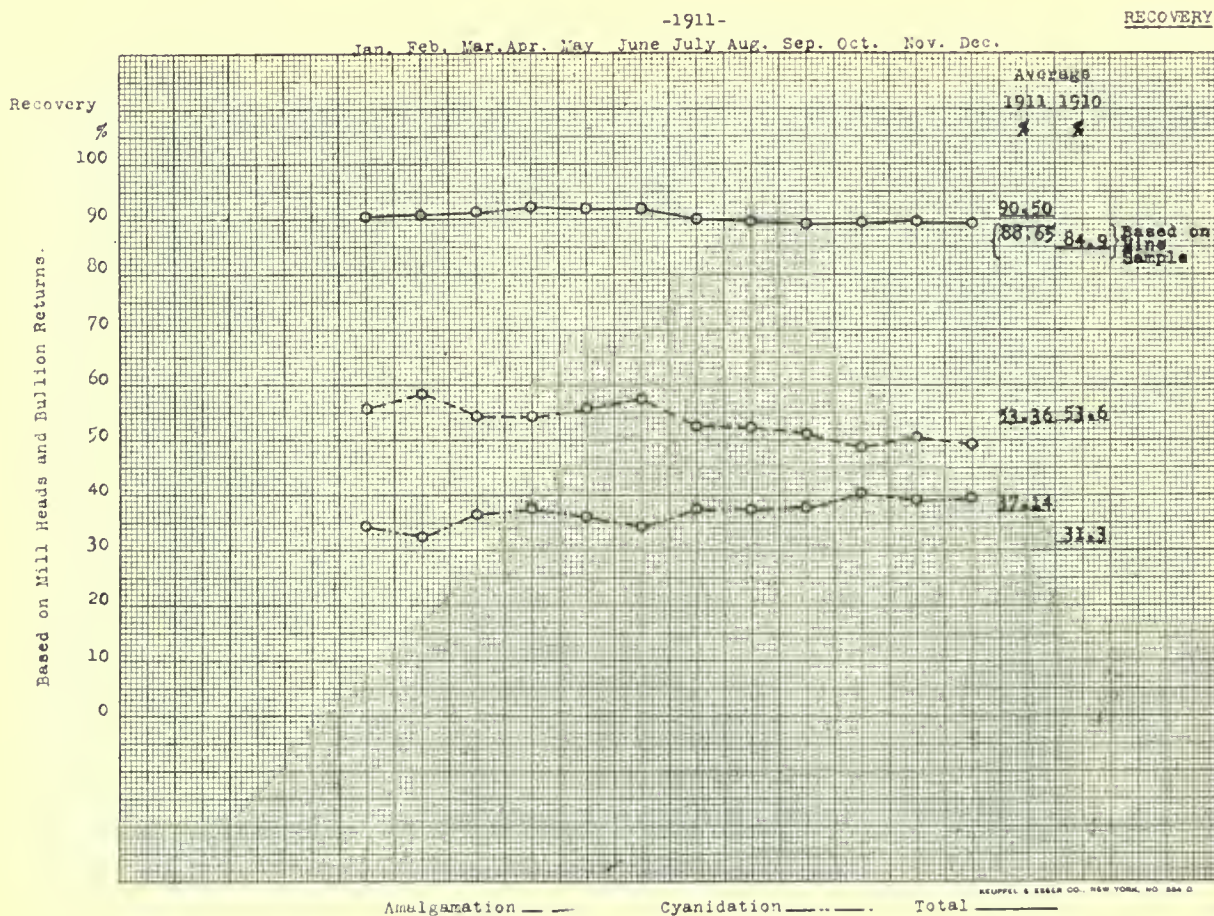

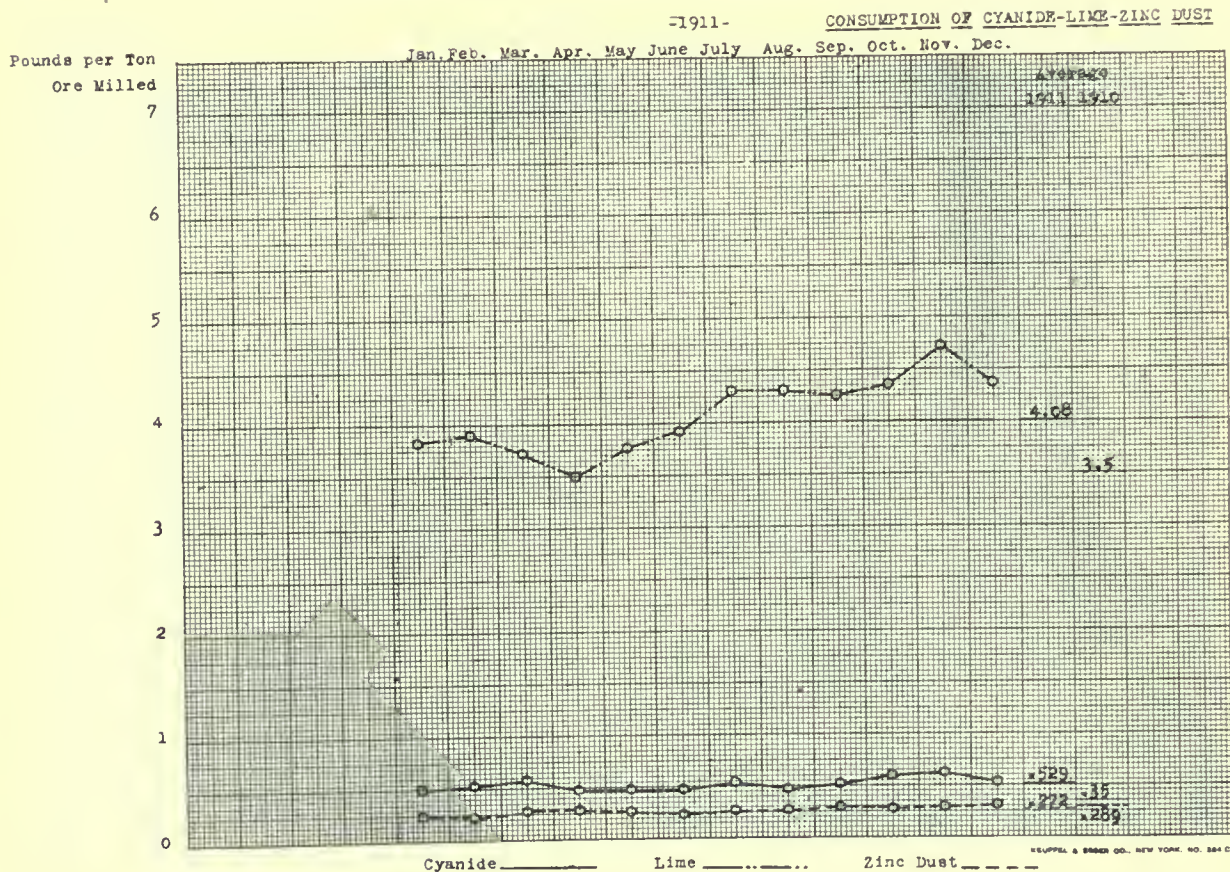

The use of a 'pro-general' and 'suspense' account, is explained in Mr. Juessen's article to which reference has already been made. Costs by the month are shown in great detail in the following diagrams, prepared by Mr. Kidder.

**Mining and Scientific Press*, May 8, 1909, republished in 'More Recent Cyanide Practice,' pp. 263-273, 1910.

Problems in Modern Copper Smelting

By S. E. BRETHERTON

*As copper is the most interesting of the base metals, its importance in the commercial world being augmented by the wonderful science of electricity, I will discuss its metallurgy; only attempting to describe modern copper smelting, which is more important for advanced students. When I say 'modern', I mean within the last thirty years. Less than thirty years ago such mines as the United Verde of Arizona, the copper mines of northern California, and others, were considered of little value because the ore was sulphide and considered refractory. Such properties were examined by several noted engineers and rejected, even at a comparatively low valuation. Today such mines have become the basis for the cheapest and best metallurgical work in the world.

For several years the Dominion Copper Co. of Globe, Arizona, hauled a trainload per day of sulphide ore all the way from Bisbee to Globe, Arizona, several hundred miles, in order to get the sulphide to make copper matte for converting. Not only this: it enabled them to make a much cleaner slag than is possible when smelting directly to black copper. I can remember the time when at Clifton and Globe, Arizona, Santa Rita, New Mexico, and other places, rich oxidized copper ore was smelted to pig copper, reducing a comparatively small tonnage in the furnace, using 20 to 24% fuel, and throwing a slag over the dump containing 2 to 3% copper, worth \$6 to \$9 per ton. Today the average slag thrown over the dump will not exceed, I think, 60c. per ton in copper, and the fuel used in the blast-furnace from 1 to 10%, depending on the sulphur contained in the ore and the character of the slag to be made. Briefly, the advantages of smelting sulphide copper ores are as follows:

1. Greater capacity for the same sized blast-furnace.
2. Less danger of 'freeze-ups', a term generally used by the smelter-men when the furnace is lost by incrustations forming from any cause.
3. Smaller fuel consumption.
4. Cleaner slag.

I might add the saving of roasting the ore. When smelting direct to black copper, it was necessary to roast any rich sulphide ore. For some time after the system of smelting to copper matte was in general use, it was thought necessary to roast most of the sulphides, and more fuel was used than at present, but as the method was improved, first with the aid of hot blast, and then cold blast under higher pressure, the percentage of fuel was continually reduced until, in some cases, smelting in the blast-furnace to a low-grade matte was accomplished without any fuel.

I have just referred to 1 to 10% fuel in the charge in matte smelting, depending on the percentage of sulphur and character of the slag to be made. If the percentage of sulphur is low, it is necessary to use more fuel to furnish the required heat and save the sulphur for matte making. Again, if it is necessary to make a slag low in iron and high in magnesia, alumina, barium, or zinc oxide, a much greater heat is required to keep it fluid. A slag chiefly containing iron base requires less heat than when the iron is replaced with an alkaline base (manganese is generally classed as iron for fluxing purposes), but it is necessary to study the specific gravity of the slag, in order to get a good matte separation, and at times in running customs plants I have had so little iron, and so much zinc and barium or perhaps magnesia and alumina, that it required more than the usual amount of heat to keep the slag hot enough to run properly. Too much iron base means a fluid slag, but too heavy for a good matte separation; too little iron and too high a percentage of alkaline bases, especially magnesium and barium, requires more heat, and

is also too viscous, holding matte or shots of metal suspended mechanically. Slag containing too much silica and alumina will do the same thing, but the most treacherous slag of all is one which contains too much zinc oxide or barium, especially if they are together.

Alumina, like magnesia, is not objectionable in limited quantities. In iron smelting, alumina is classed as a base, but in ordinary copper or lead smelting I consider it safer to class it as an acid. I find it acts so for me, no doubt, for the reason that in the shallow lead or copper furnace a much lower temperature and less percentage of fuel is used than in the deeper iron blast-furnaces. In lead smelting the metallurgist has very little margin to work on when figuring his slag; that is, he cannot depend on getting any iron from unroasted sulphides; if he did, the volatilization of lead would be too great, causing serious losses, and he must be careful to watch his silica so as not to form silicate of lead in the slag. The copper metallurgist does not fear the volatilization of copper or the formation of silicate of copper; in fact, a silicious slag for copper smelting does cleaner work and is more suitable for fire concentration. But if he depends on getting all his iron for slag-making purposes from raw sulphides, as I have frequently had to do, it is necessary, after figuring the charge, to see that his instructions are carried out on the feed floor, for too much fuel, too deep burden, or too small a volume of blast might mean a freeze-up, due to lack of iron in the slag. The shape of the furnace, the size and number of the tuyeres, the way the furnace is fed, all have some bearing on this question, as well as the amount of the blast used. The size and character of the ore has also to be considered.

Fine ore is very objectionable in blast-furnace work (here comes in the question of the proper method of crushing and sampling). Reverberatory smelting practice has the advantage over the blast-furnace in smelting fine ore, but the ore has to be all crushed fine and a preliminary roast given it. I have also found that very little zinc can be volatilized in the reverberatory furnace, whereas I have volatilized over 40% of it in the ordinary blast-furnace, which is a great advantage when the ore contains more zinc than the slag can carry. You have doubtless read articles describing the necessity of roasting matte before re-smelting in order to get a matte richer in copper for either the converter or for marketing direct. I remember an article written several years ago by one of our prominent metallurgists, claiming that the re-smelting of matte in the blast-furnace without roasting did not increase its copper content by concentration. My experience for several years has been, both in Arizona and California, to ship matte containing 30 to 40% from ore in Arizona, averaging about 11½% copper, and in California 3%. This means a concentration of 20 and 13 tons of ore to 1 ton of matte, respectively, requiring a re-smelting of this matte with silicious ore, a re-smelting which was made more difficult on account of having a poor quality of silicious ore on hand to work with.

This roughly outlines the principles of copper matte smelting down to where the converter is used. To make this clearer, it will be necessary to describe each particular feature I have taken up in detail. Some of you may be called upon at some time in the future to decide as to the advisability of erecting a small smelter for a partly developed mine, perhaps some distance from a railroad, the owners having read about 11½% copper in 'porphyries' paying dividends where the ore is first concentrated and then smelted in the reverberatory or blast-furnace, or about where 2½ to 3% copper sulphide is made to pay dividends by direct smelting to matte and then converted to blister copper containing the silver and gold which is

*An address delivered before the Mining Association of the University of California, January 24.

shipped to Eastern refiners for further separation.

It may be well here to put in a word of caution. Converting the matte to blister copper means a saving in freight on waste, such as iron and other sulphides contained in the matte, and also a better price for the copper of 1 to 1½c. per pound, but it is not practicable to operate a converting plant in connection with a small matting plant, so that unless the ore contains much precious metal to help the copper carry the expenses, and conditions are unusually favorable, it is often better to ship the crude ore and put in no reduction plant at all. It is true that some of our largest and best paying copper properties of today, such as the United Verde, and Copper Queen of Arizona, the copper smelters of Montana, and others, which could be mentioned, were started as copper matting plants.

To illustrate this point: Some time ago I was called upon to examine property 45 miles from the railroad. The owners felt sure they had a good property which could be made to pay handsome profits with less than 3% copper. The cost of marketing copper is greater than is generally realized, especially in the form of matte. Matte containing 40% copper is the most profitable to make, on account of slag losses, and is the most suitable for converting plants, where it is blown to blister copper. A 40% copper matte made from a 3% ore would equal a concentration of 14 tons of ore into 1 ton of matte, allowing for about 5% loss of copper in smelting. The expense on this ton of matte would be, estimating copper at 15c. per pound: Wagon haul as back freight, 42 miles, not less than \$6; shipping to Salt Lake City (the nearest market), railroad freight, \$5.25; copper refining deduction, 2¾c. per pound, \$22; copper deduction, wet assay, 1.3%, \$3.90. This amounts to \$37.15 per ton of matte, which, divided by 14 tons, equals \$2.65 per ton of ore. Estimating mining and all development expenses at least \$2.50 per ton of ore; general and all offices expense at 35c. per ton; smelting so far from a railroad, \$3 per ton, at the very least; made a total of \$8.50 per ton, even on the basis of a comparatively large plant. Divide this by 60 lb. of copper, less 5% for loss, or 57 lb., the cost would be 14.93c. per pound, in round numbers 15c. Usually copper ore contains precious metals to assist the copper in carrying the expense, but in this particular case the gold and silver content was scarcely worth considering.

The method of concentrating matte to metallic copper in the converter was the greatest advance in copper metallurgy within the last thirty years. The refining of copper by electricity can perhaps be classed as the second most important advance. The practice of converting copper matte has been constantly improved since being first introduced at Butte, Montana. The use of silicious ore for lining, instead of barren quartz and clay; larger converters; machinery for tamping; and, last but not least, the long-wished for method of adding silicious ore to the converters, as required, is now being accomplished successfully, by using a basic lining and adding the silicious ore instead of depending entirely upon the lining to furnish the silica required for combining with the iron in the matte as the sulphur is oxidized and driven off.

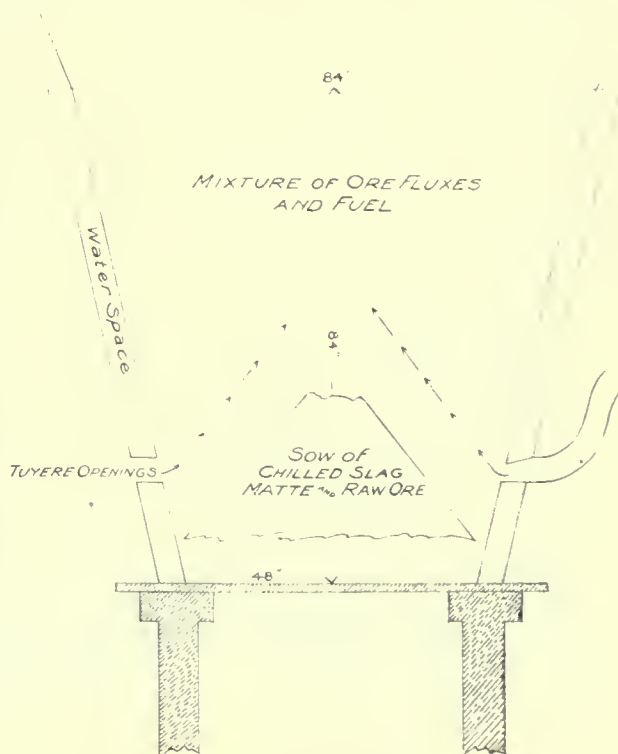

The great success and continued improvement in converting practice have had considerable bearing on blast-furnace and reverberatory smelting practice. To some extent the same principles are applied in the much higher blast pressure and larger volume of blast now used. The higher pressure and deep shaft furnaces for copper matting can be used where ores are comparatively clean, but my experience has been in the smelting of ore containing high percentages of zinc that it was necessary for us to carry a very low burden above the tuyeres, with an extremely hot top, otherwise the incrustations would form so quickly on the walls of the furnace that the furnace would have to shut down in order to be barred off. The shape of the furnace has considerable bearing on this question also. For this reason I have planned a blast-furnace, especially designed for the smelting of refractory ore containing zinc, shown in the accompanying illustration.

The extremely large top of this furnace is to allow the

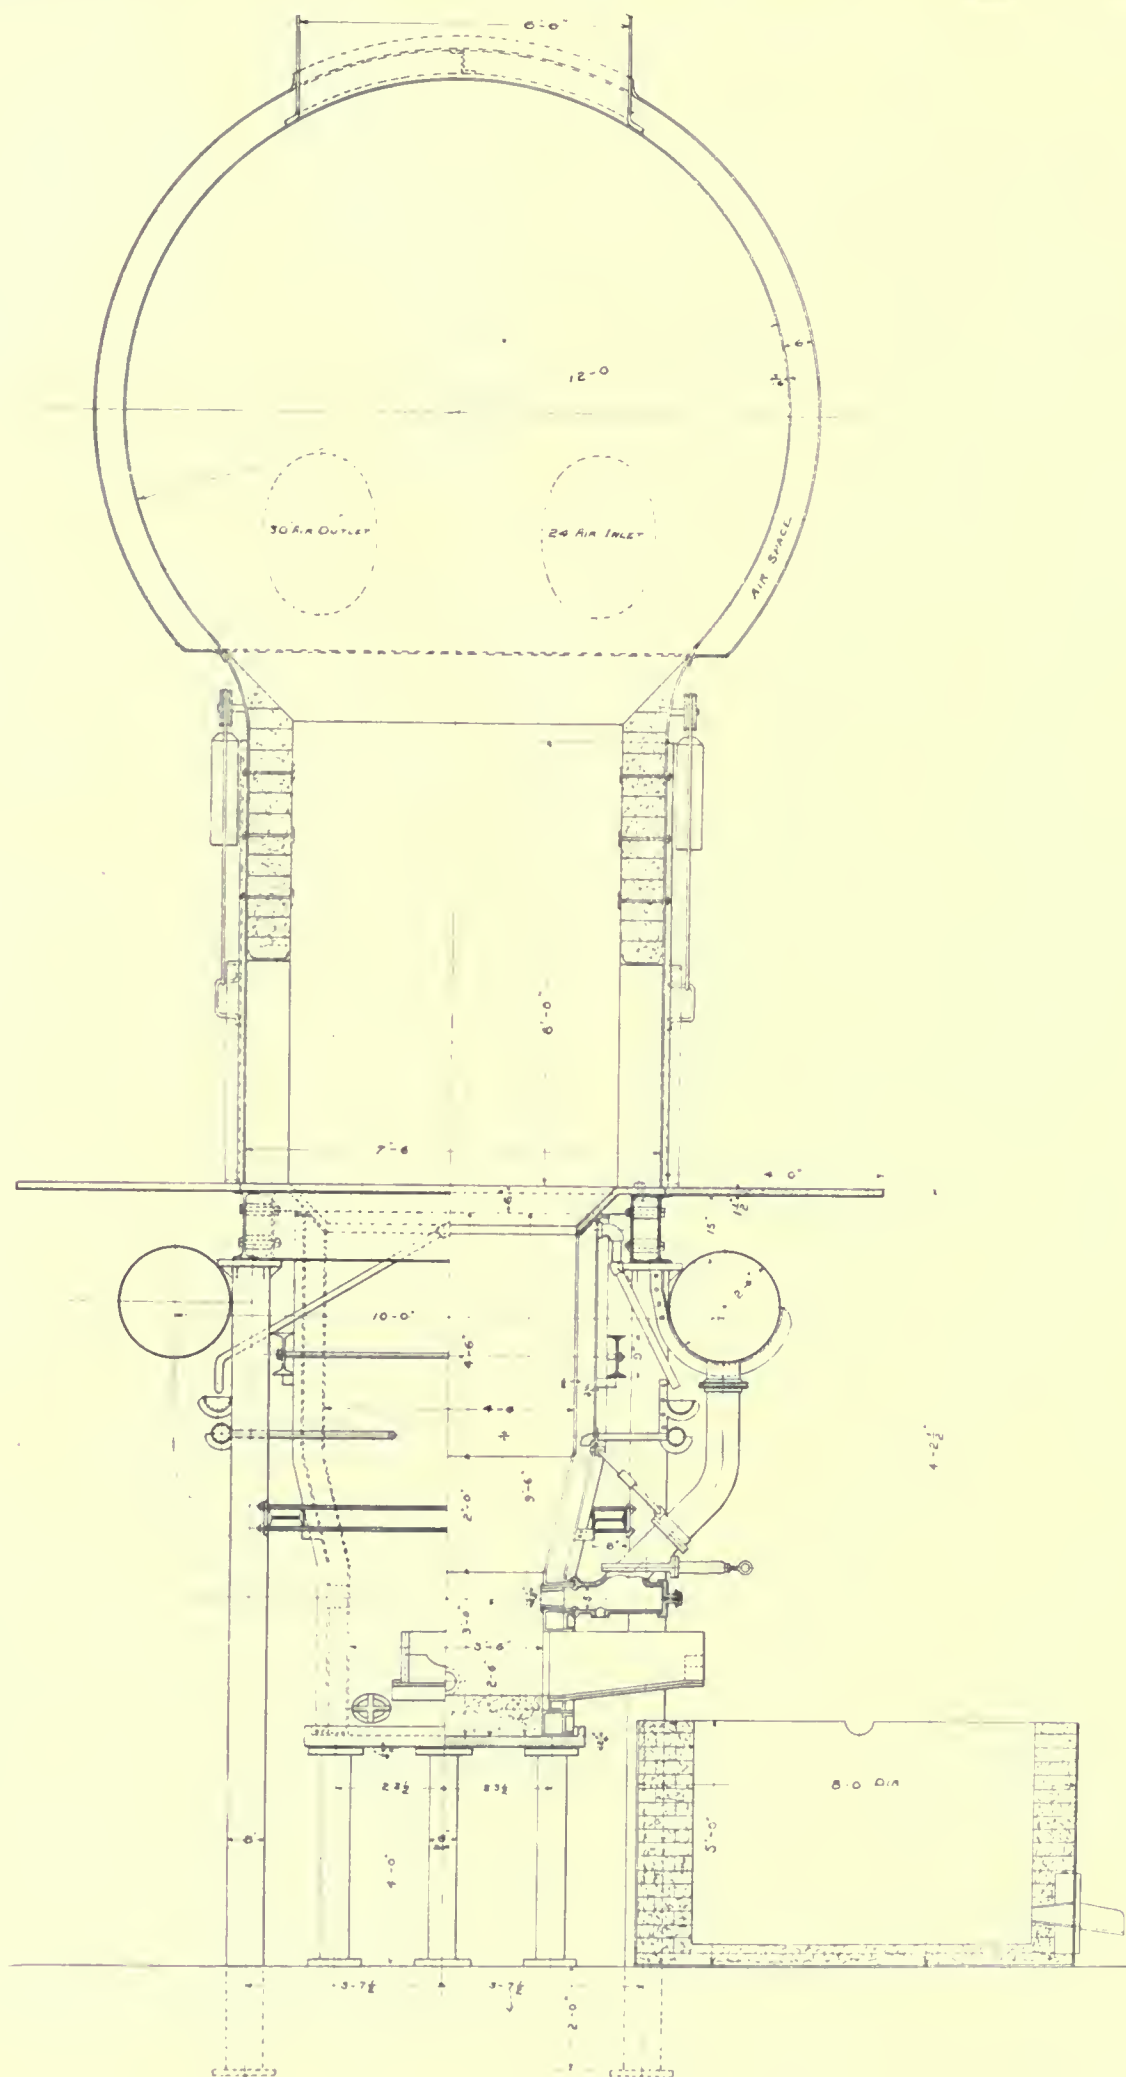

dust to fall back on the charge, which results from the fume passing through this increased area and decreasing its speed just before entering the smokestack. This was found to be a great advantage. The dust, which is mechanically thrown out by high blast-pressure and usually goes over into the dust chamber, was found to be very much lessened by the use of this enlarged top. There is a 6-in. space or shell surrounding this top, which is for blast-heating purposes. This feature was added only at the request of those for whom I was designing the furnace, as I do not consider the results obtained justify the expense. By this arrangement the space required for feed doors is cut out, the heating surface is not very great; then again, the interior of this shell, exposed to the hot fumes, quickly becomes coated with dust, which is a poor conductor of heat. The greatest advantage of this air chamber above the feed floor would be the benefit of the cooling effect to the men working on the feed floor. Of course, this can also be obtained by brickwork.

In the body of the furnace below the feed floor, it is only 7 ft. from the centre of the tuyeres to where it is possible to carry the top of the charge, which is much lower than the ordinary type of blast-furnace, but this furnace was especially designed for the smelting of ore containing zinc. The bosh, starting a few inches above the tuyeres, only extends up a distance of 2 ft.; from there to the top of the furnace the walls are perpendicular. I found this a great advantage, for the reason that the smelting zone belongs between the tuyeres and for a few feet above them. By allowing the weight of the charge to be carried by the boshes it keeps the pressure off the crucible and allows freer circulation of the blast between the tuyeres, at the same time holding the burden more compactly above. The following, showing the shape of one of the first blast-furnaces I was requested to use in copper smelting, illustrates my reasons for this, and while it was very provoking at the time, the experience taught me a valuable lesson.

The total height of the furnace from crucible to feed floor was about 9 ft. diam. at the top, 4 ft. at the tuyeres, with a continuous slope from the top to the bottom. The ore was the ordinary silicious copper ore with iron and zinc sulphides, containing some zinc and as much iron as we cared to use. After operating for a few hours, the smelting zone was all at the top of the furnace, slag and matte in the crucible, too cold to run, and a cone or sow formed, as shown in the sketch. This was due to the blast passing up the sides of the furnace instead of reaching the

CROSS-SECTION OF A POORLY DESIGNED BLAST-FURNACE.

centre of the charge. It followed the lines of least resistance, blowing the heat with it and leaving an unfused centre between the tuyeres above the crucible, which kept growing larger until the furnace was lost. What little smelting was done the last few hours the furnace was kept alive was between the centre and the walls, the slag dropping into the crucible near the outer rim, which we found to be the cause in cleaning out the furnace. This furnace was afterward abandoned and has never been used since, to my knowledge. The man who designed this furnace had had some practical experience, and I was very much surprised at his making such a blunder.

Some metallurgists advocate very wide blast-furnaces, even as much as 56 in., but this is only possible where the ore is coarse, having had the finer material removed by screening, and a considerable depth of burden is carried above the tuyeres. There is a limit to the coarseness of the ore as well; more especially in smelting ore containing zinc in shallow furnaces. As zinc sulphide is one of the most infusible ores, it is necessary to oxidize it so as to volatilize the sulphur and form zinc oxide. For this reason it is evident that in shallow furnaces the centre of any large lump of ore would pass into the crucible where oxidation ceases, and there accumulate until the furnace is lost, unless a good foreman stops the blast, takes out the breast, draws off all such accumulations, replaces the breast, and resumes operations. It will be evident to those of you who have had some practical experience that the blast entering at the side of the furnace will have a tendency to ascend while passing through the charge to the centre; so that if the furnace is too wide or the charge too fine, what is commonly known as a 'sow' will form in the centre of the furnace in the shape of a cone. This will mean the loss of the furnace in time, as it forces the blast with the heat away from the crucible and too much to the top of the furnace. Before this becomes serious there are generally one or more large blow-holes formed in the charge above the tuyeres, through which the blast escapes like wind forced up a chimney. It is the prevention of these blow-holes by proper feeding, which requires some of the feeder's skill.

Much zinc is always objectionable, but it can be handled to better advantage in copper smelting than in lead smelting; in fact, zincblende seems to give less trouble in a blast-furnace with hot-blast than when roasting in a reverberatory furnace, as it requires much more heat to liberate its sulphur than when roasting pyrite; and it must be that with hot-blast the oxygen, not having to unite with fuel, has a better chance to combine with the sulphur where such an intense heat exists as in the blast-furnace. Some metallurgists claim that no copper is necessary, and an iron matte will save the precious metals present. Mixtures containing much less iron and more silica can be smelted to better advantage than those I have named; but it would require too long to discuss the question of the different combining powers of each base with silica, to form singulo-silicates for lead smelting or bi-silicates for copper smelting.

The first heat required is for heating the air-blast up to the temperature where the oxygen will combine with either the carbon of the coke or the sulphur contained in pyrite; then the heat necessary for melting ores and fluxes so that they will combine to form the proper silicates for fluid and clean slag is produced by the oxidizing of the fuel in the charge by the oxygen in the blast. If cold-blast is used, the free oxygen going in with it is required to oxidize the extra fuel required to heat the blast, thus leaving little for the sulphur. If more cold-blast is used so as to get still more free oxygen, it drives the heat still farther away from the tuyere openings into the furnace, and reduces the smelting area of the furnace in that proportion, driving the heat higher up in the furnace and burning the fuel and smelting the ore so near the top of the furnaces that any metals volatilized have no chance to get caught. It keeps the fuel burning so high above the tuyeres that it leaves very little for the blast to encounter as it enters, unless a large quantity is used. When the cold-blast enters the furnace and encounters hot charge without fuel mixed with it to generate heat, a crusted fur-

nace soon results, starting at the tuyere nozzle and reducing the capacity of the furnace until it is closed. This results when too much cold-blast is used, or too little fuel and sulphur are used with the cold-blast. By the use of the hot-blast this trouble is greatly decreased and the hotter the blast is the better it is, up to a point where all the heat necessary for smelting can be produced by the combination of the oxygen in the blast with easily oxidized elements in the ore, such as sulphur and arsenic. When these elements are not in sufficient quantity to produce by oxidation the heat required without making too high a concentration; that is, when there is not enough sulphur to make matte for the regular clean working of the furnace, then sufficient fuel should be used in order to save the necessary sulphur for making a proper grade of matte.

Petroleum Products in Siam

By CARL C. HANSEN

The total imports of refined kerosene into Siam for the fiscal year ended March 31, 1911, amounted to 6,300,768 gal., worth \$797,123, of which 1,843,856 gal., value \$250,056, came from the United States, 4,452,072 gal., value \$546,026, from Sumatra, and 480 gal., value \$1041, from Singapore. The Asiatic Petroleum Co. (Ltd.) has two brands of oil in the market, the 'Dragon' and 'Crown,' which retail at 54 and 56c. per tin of 5 gal., respectively; and the Standard Oil Co. exploits three brands of kerosene, the 'Eagle,' 'Cock,' and 'Devon,' the retail prices being 54c., 59c., and \$1.67 to \$1.85 per tin of 5 gal., respectively.

The imports of benzine for the last fiscal year amounted to 209,660 gal., of which 89,320 gal., value \$24,208, was imported from the United States, being retailed under the name 'Pratt's motor spirit' at \$1.39 per tin of 5 gal.; and 120,340 gal., value \$34,901, came from Sumatra, being known in the market as 'Shell motor spirit' and retailed at the same price as the Pratt. During the year under review 673,527 gal. of fuel oil, value \$25,578, was also imported from Sumatra. The total value of the imports of lubricating oil for the fiscal year ended March 31, 1911, was \$59,109, and of this amount the United States contributed \$39,214 worth. Great Britain's share was \$10,716. The yearly imports of petroleum oils, including kerosene, benzine, and fuel oils, for the five fiscal years from 1907 to March 31, 1911, inclusive, have amounted to 5,362,822, 6,123,041, 6,294,167, 6,610,601, and 7,183,955 gal., respectively. Of other petroleum products, candles to the value of \$33,227, nearly all of which came from Burma, and wax valued at \$66,714, were imported during the year ended March 31.—*Daily Consular Reports.*

Idle Mining Property

The remedy for the existing evil of idle mining property must be sought either in the adoption of leasehold, under which the Government can enforce operation, a system which fully attains the desired end of promoting mining development in Australia and New Zealand, according to the report in 1907 by A. C. Veatch, geologist of the Geological Survey, to the President, or in the thorough revision of the existing system. Radical amendment to the present law would be necessary in order to secure something more nearly approaching equality of opportunity. Some limitation should be put on the number of claims which an individual can locate in each mining district, and the prevention of monopolization would be furthered by the rigid enforcement of assessment development. The record of claims kept by a local official elected by the miners should be reported to the nearest land office in order to furnish the Federal Government with a notice of the intention of the claimant, and thus to initiate the operation of effective inspection, the purpose of which would be to enforce the use and development of mineral land as contemplated in the law. (From Report of Director, U. S. Geological Survey.)

Bureau of Mines Act

The chairman of the House Committee on Mines and Mining, M. D. Foster, has introduced a bill amending the Act governing the Bureau of Mines so that it will read:

"That there is hereby established in the Department of the Interior a bureau of mining, metallurgy, and mineral technology, to be designated the United States Bureau of Mines, and there shall be a director of said bureau, who shall be thoroughly equipped for the duties of said office by technical education and experience and who shall be appointed by the President, by and with the advice and consent of the Senate, and who shall receive a salary of \$6000 per annum; and there shall also be in the said bureau such experts and other employees, to be appointed by the Secretary of the Interior, as may be required to carry out the purposes of this Act in accordance with the appropriations made from time to time by Congress for such purposes.

"Section 2. That it shall be the province and duty of the Bureau of Mines, subject to the direction of the Secretary of the Interior, to conduct inquiries and scientific technologic investigations concerning mining, and the *preparation, treatment and utilization of mineral substances*, with a view to *improving the health conditions of the operators and increasing safety, efficiency, economic development*, and the prevention of waste in the mining, quarrying, metallurgical and other mineral industries, and concerning explosives and fuels and unfinished mineral products belonging to, or for the use of, the United States, with a view to their most efficient use; and to *disseminate information* concerning these subjects in such manner as will best carry out the purposes of this Act.

"Section 3. That the director of said bureau shall prepare, publish, and distribute, subject to the direction of the Secretary of the Interior, under the appropriations made from time to time by Congress, reports of inquiries and investigations, with appropriate recommendations of the bureau, concerning the nature, causes, and prevention of accidents, and the improvement of conditions, methods, and equipment with special reference to health, safety, and prevention of waste in the mining, quarrying, metallurgical, and other mineral industries; the use of explosives and electricity, safety methods and appliances, and rescue and *first-aid work in said industries*; the causes and *prevention of mine fires*; and other subjects included under the provisions of this Act.

"Section 4. That nothing in this Act shall be construed as authorizing the Bureau of Mines or any employee of said bureau to undertake any investigation or operation in behalf of any private party, except with the approval of the Secretary of the Interior, for the health and safety of persons employed in the mining, quarrying, metallurgical or other mineral industries; nor shall the director or any member of said bureau have any personal or private interest in any mine or the products of any mine under investigation: Provided, that nothing herein shall be construed as preventing the employment by the Bureau of Mines, in a consulting capacity or in the temporary investigation of special subjects, of any engineer or other expert whose principal professional practice is outside of such employment by said bureau.

"Section 5. That for tests or investigations authorized by the Secretary of the Interior under the provisions of this Act, other than those performed for the government of the United States or state governments within the United States, a reasonable fee covering the necessary expenses shall be charged, according to a schedule prepared by the Director of the Bureau of Mines and approved by the Secretary of the Interior, who shall prescribe rules and regulations under which such tests and investigations may be made. All moneys received from such sources shall be paid into the treasury to the credit of miscellaneous receipts.

Section 6 is the usual emergency clause.

Proposed Change in the Lead Tariff

By W. A. SCOTT

The Underwood bill passed the House of Representatives on January 29, and in amended form probably it will pass the Senate. By the provisions of this bill, as it passed the House, zinc and zinc in ore produced in foreign countries may be received in American markets free of duty; pig lead and lead in ore, instead of being charged a specific duty of 2½¢, per pound as under the old schedule, is subject to a duty of 25% *ad valorem*. The lead and zinc producers of Idaho, Utah, Colorado, Missouri, and Kansas foresee lower prices of those metals as the result of a law that would give foreign producers such easy access to our markets as does the Underwood bill. The secretary of the American Mining Congress, who is at Washington, is being supplied with data by Western operators wherewith to try to defeat the measure in the Senate. The most united protest undoubtedly emanates from the Coeur d'Alene district, Idaho, where some of the largest lead-silver mines of the world are situated. That the ores of this region are not as high grade as were those formerly produced is shown by the fact that the portion that requires concentration before shipping constitutes an ever-increasing tonnage, while there is a corresponding decrease of the tonnage of shipping grade. The Idaho operators believe that the proposed reduction of duties will result in supplying the American market with lead from Mexico and Spain to such an extent as to depress the price below \$4 per hundred. With lead at present prices there is special activity in the development of lead mines in northern and central Idaho, and in Park City and Tintic districts, Utah; but if there should come a pronounced drop in the price of lead, it is certain that this activity on new properties would be checked to a marked degree.

The manufacturers of lead pipe and similar commodities probably have made their influence felt in fixing the lead schedule in the Underwood bill, and it is probably true, as claimed, that American owners of lead mines and lead smelters in Mexico would welcome the changes provided for in the Underwood bill, as the new schedule would enable them to make a profit on their Mexican product even with lead at prices that would mean a loss to many of the Utah and Idaho operators. While the Guggenheims have nine lead-smelting plants in the Western states, their actual interests in mining properties are comparatively small. Their chief interest today in the Coeur d'Alene, in Utah, and in Colorado consist of smelting contracts; and since the International Smelting & Refining Co. joined the United States and Salida companies as competitors of the A. S. & R. Co. for the purchase and smelting of lead ores, the last-named concern is losing some of its big customers and is no longer in position to dictate smelting rates. It is, therefore, only business tactics on the part of the A. S. & R. Co. to so aid in framing duties as to let in cheaper ores for their American smelters, and afford an open market for the pig lead produced at their five smelting plants in Mexico. It should not be forgotten that, while the Guggenheims own and operate chiefly smelters in the United States, they own and operate not only smelters but mines in Mexico. In the practical workings of the Underwood law, our lead-mine operators might be cramped by low prices of lead, while the smelting company, which has no mines, could import ores from Spain at prices that would enable it to adjust itself to almost any market price of lead. It is not likely that a great tonnage of lead ore would be shipped from Mexican mines to smelters in the United States in the event of the Underwood bill becoming a law, because Mexico has not less than ten lead smelting plants, and with the abundance of coal and coke in that country, and the cheaper labor, its smelting as well as mining operations are on a more economical basis than are those of the United States. It is probable that the old lead duty will not be retained

Annual Meeting of the A. I. M. E.

A circular letter recently distributed calls attention to important issues bearing on the future development of the American Institute of Mining Engineers which will be decided at the annual meeting, which is to be held at the headquarters in New York City, 29 West 39th street, on February 19, 20, and 21. It is proposed hereafter to make the annual meeting the most important gathering, professionally and socially, of the year, and all are urged to make an effort to participate. Local committees have been organized, and a detailed program will be issued at an early date. The circular is signed John Birkinbine, D. W. Brunton, S. B. Christy, James Douglas, James Gayley, John Hays Hammond, H. M. Howe, Robert W. Hunt, C. Kirchhoff, W. A. Lathrop, B. B. Lawrence, A. R. Ledoux, E. E. Oleott, R. W. Raymond, J. W. Richards, E. G. Spilsbury, and Gardner F. Williams. The annual business meeting of the Institute will be held at the Institute headquarters on Tuesday, February 20, 1912, at 10 o'clock a.m. At this meeting members present, or by proxy, will elect a president, vice-president, secretary, and three members of the council, and three directors of the corporation: as required by the constitution. A form of proxy, in the name of Leonard Waldo and Bradley Stoughton, has been sent to qualified voting members, which may be signed, witnessed, and returned to the office of the Institute, with or without alteration. Members and associates in arrears for dues of 1911, or residing outside of the United States, Canada, and Mexico, are not entitled to vote. The following names, comprising all the nominations received for the offices of the council, have been recommended by the nomination committee, which consisted of E. Gylbbon Spilsbury, James R. Finlay, Charles P. Perin, Arthur S. Dwight, and Louis D. Huntoon. Said nominations were approved by the council at the regular meeting, January 12, 1912.

For President of the Council—James F. Kemp, New York, N. Y. (term expires February 1913).

For Vice-Presidents of the Council—Benjamin B. Thayer, New York, N. Y.; Karl Eilers, New York, N. Y.; Waldemar Lindgren, Washington, D. C. (term expires February 1914).

For Secretary of the Council—Joseph Struthers, New York, N. Y. (term expires February 1913).

For Members of the Council—Joseph W. Richards, South Bethlehem, Pa.; John H. Janeway, Jr., New York, N. Y.; Sidney J. Jennings, Dobbs Ferry, N. Y. (term expires 1915).

The arrangement for the meeting, apart from the technical sessions, are in the hands of the New York local section, the executive committee, which consists of Benjamin B. Lawrence, James Douglas, Bradley Stoughton, C. P. Perin, and George F. Kunz. All inquiries concerning local matters, except those referring to papers and discussions for the technical sessions, should be addressed to Bradley Stoughton, 165 Broadway, New York. The control of the papers and discussions will be exercised by the president and the secretary of the council, as usual. Details of the technical sessions of the meeting will be given in the program of the local committee, which will be furnished to each member or guest on registration at headquarters. Members wishing to visit during the week of the meeting any industrial plant or work in New York City or vicinity will be assisted to do so by means of suitable introductions and guidance, upon timely notice given by them in advance to George Buckman, 29 West 39th street, New York City.

The following provisional program has been arranged, subject to possible but not probable change by the local committee:

Monday, February 19, 1912:

8:15 p.m.—Informal social meeting at Institute headquarters, beginning with an illustrated lecture on some topic of popular scientific interest.

Tuesday, February 20, 1912:

10:00 a.m.—Annual business meeting.

12:30 p.m.—Luncheon at the Engineering Societies building.

2:00 p.m.—Technical session.

7:00 p.m.—Banquet at Hotel Plaza, 59th street and Fifth avenue. committee: James Gayley, A. R. Ledoux, D. M. Riordan, Theodore Dwight, and Thomas Robins.

Wednesday, February 21, 1912:

10:00 a.m.—Technical session.

12:30 p.m.—Luncheon at Engineering Societies building.

2:00 p.m.—Technical session.

A Possible Oilfield

It will be remembered that, following suggestions of the State Geological Survey of Illinois as to geological structure, a new field was brought in last year near Carlyle. In the year since, southern Illinois has been re-studied by E. W. Shaw, recently of the geological corps of the Southern Pacific and now working jointly for the Illinois and the United States Geological Surveys. He has found a number of places where the structure is favorable to oil accumulation, and, in advance of a complete report, the following list of such localities has been announced as worthy of being tested for oil and gas: The vicinity of Darmstadt, northeast of Lenzburg; about Marissa and extending for several miles toward Oakdale; between Nashville and Addieville; the vicinity of Hoffman; between Mascouta and Okawville; between Trenton and Breese; in a belt extending a few miles north to a few miles south of O'Fallon; the central part of Irishtown township northeast of Carlyle; and one to three miles northeast of Bartleso.

The circular distributed says: "A more exact statement of positions and limits of the likely districts must await further study. It is not to be assumed that all of these districts mentioned contain pools of oil or gas, but only that conditions seem to be much more favorable than in surrounding territory. The oil and gas pools of Illinois have all been found in districts where the geology is similar to that in those enumerated above, but there are many such districts where no oil and gas exists. Judging from these facts, it would appear likely that if any oil is found outside the districts mentioned above it will be where there are similar conditions but where the geology is so obscure that they have not yet been discovered."

Government Assays Free

The proposal contained in a bill recently introduced in Congress, that the United States Government shall furnish assays at a nominal charge, has provoked prompt opposition. At a meeting of the principal assayers and metallurgists of San Francisco, held February 5, 1912, the following resolution was unanimously adopted: *Whereas*, a bill, H.R. 17,033, has been introduced by Mr. Raker of California into Congress and referred to the House Committee on Mines and Mining, providing for the establishment of a government experiment station at Auburn, Placer county, California, at which assays, tests, analyses, and miscellaneous investigations of minerals and metallurgical problems are to be made gratuitously or for a nominal charge, and, *whereas*, there already exist well established private plants where this work is adequately and economically done and which meet the existing conditions along these lines.

Now, therefore, be it resolved, that while cordially approving of well directed efforts on behalf of the Government in the advancement of science, we protest against any unnecessary interference with established industry and personal initiative and against this bill in particular, as an unwarranted and unwise incursion into the field of established business. *Be it also resolved*, that copies of this resolution be sent to Congress, to the press and to interested technical societies.

THE production of the ruby mines of Mogok in 1910 was 260,019 carats, valued at about \$520,000. This was an increase in weight of 4715 carats over the previous year, but of only \$1000 in value. The number of laborers in the ruby mines during the year on the per diem roll was 1463.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

American Institute of Mining Engineers

The Editor:

Sir—On January 27 a meeting was held in Washington of the members of the American Institute of Mining Engineers who are also members of the U. S. Geological Survey to consider the proposed amendments to the constitution of the Institute. At this meeting were present G. H. Ashley, G. F. Becker, A. H. Brooks, E. F. Burchard, R. H. Chapman, Frank L. Hess, W. Lindgren, H. D. McCaskey, E. W. Parker, F. L. Ransome, C. E. Siebenthal, George Otis Smith, A. C. Spencer, D. B. Sterrett. Arnold Hague was prevented from attending, but he, as well as George P. Merrill, of the National Museum, and J. A. Holmes, of the Bureau of Mines, desires to express his concurrence in the action taken.

The following resolutions were passed after full discussion and without a single dissentient vote: (1) The members of the American Institute of Mining Engineers present do not approve of the proposed change of name of the Institute to 'American Institute of Mining and Metallurgy.' (2) The members of the American Institute of Mining Engineers present are not in favor of the change in classification of members on the basis proposed in the circular, which is not a re-classification based upon professional standing. (3) In the absence of a financial statement showing that an increased income is necessary, the members present are opposed to the proposed increase in dues. A committee was also appointed to communicate the resolutions to the mining press in the hope of eliciting expression of opinion from other members of the Institute.

WALDEMAR LINDGREN,

GEORGE F. BECKER,

A. H. BROOKS,

Committee.

Washington, D. C., January 30.

[The above letter shows a healthy interest in the affairs of the Institute, as does also the following, which has been sent to members with request for proxies made out in the name of G. C. Stone and J. R. Finlay. It is evident that the meeting to be held in New York this month will be most important and we again urge every member who can do so to attend in person.—EDITOR.]

To the Members and Associates of the

American Institute of Mining Engineers:

Sirs—At the annual meeting of the A. I. M. E. in New York, on February 20, radical changes in its constitution are to be considered. Among these is a proposal to increase the dues of all corporate members. We, the undersigned, intend to vote against an increase of dues, and we ask the coöperation of members unable to attend the forthcoming meeting, who are of the same mind in this matter as we are. The reasons for an increase of dues offered officially by the secretary of the Institute are, in our opinion, vague and unsatisfactory. Without denying that an increase may be advisable, we propose to contest such a measure until full information respecting the situation has been communicated to all members of the Institute; and until after it has been determined by a careful investigation of the Institute's affairs that the same purpose cannot be accomplished by economies in administration. We intend to vote against the proposed increase in dues, and to offer a resolution to appoint an independent committee to study the affairs of the Institute before any further action be taken. If you desire us to vote for you upon these principles, please execute the proxy that we enclose herewith. If you have already given your proxy to some

one else, you have the right to cancel it. If you now give us your proxy you will thereby cancel all those previously given.

Automatic Zinc-Dust Feeding

The Editor:

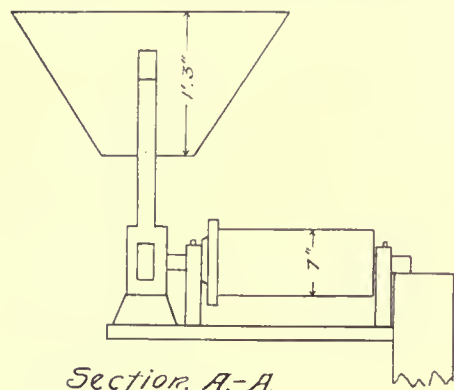

Sir—The drawing illustrates an automatic zinc-dust feeder that is being used with success at the Palmarito mine, Mocorito, Sinaloa, Mexico. It seems to possess several points of superiority over any feeder now in use. These points are: First, a positive continuous feed that is easily

and quickly regulated at the will of the operator; second, extreme mechanical simplicity; third, practically automatic action. Zinc-dust, owing to its hygroscopic properties, very readily absorbs moisture from the atmosphere, and the greater the percentage of moisture in the dust the greater its tendency to pack, and therefore the more difficulty in securing a positive feed. This was the problem to overcome here. At the low altitude of the mine, only about a hundred feet above sea-level, the air contains a great deal of moisture, and no matter how tightly closed the zinc container, it would absorb a high percentage of moisture. The feeder overcomes this difficulty and gives a positive continuous feed under varying degrees of moisture.

It may be briefly described as follows: A rectangular box, with sides sloping at an angle of 60°, made of 1-in. material lined with galvanized iron, having a central feed-compartment or slot, about 1 in. wide, that reaches to within 1 1/2 in. of the bottom of the box. This space is

left so that the dust may enter the central feed-slot from each side, but not in such quantity as to offer any resistance to the revolution of the spokes that elevate the dust. An axle, $1\frac{1}{2}$ -in. diam., has attached to it four or more steel rods or spokes, $\frac{3}{8}$ -in. diam., with recessed openings at the ends shaped so as to form an elevator bucket to raise a definite quantity of zinc at each revolution. This shaft revolves at a speed of 15 or 20 r.p.m., not fast enough to cause the buckets to throw their contents by centrifugal force, but allows them to discharge by the force of gravity alone. The buckets are recessed in such a manner that they will not discharge their content until past the centre of gravity. The rods or spokes are flattened to knife-blade thinness, so that no zinc will adhere to them in their passage through the dust. These buckets discharge into a chute, also made of galvanized iron set at such an angle that the zinc does not stick, but runs into a continuous stream into the spiral feed of a miniature tube-mill. We have adopted Yaeger's idea of a small tube-

mill to make the zinc emulsion, and find that it works well. A small stream of water washes the zinc into the feed of the tube-mill from the point where it strikes on leaving the chute.

The spokes radiating from the axle are threaded, and screw into the axle, so that in order to regulate the feed it is only necessary to take out a spoke and screw in another having a larger or smaller bucket, as may be needed to increase or diminish the feed.

To provide against the zinc in the container packing so that it will not run into the central feed-slot, a $\frac{3}{8}$ -in. steel rod slightly flattened at the ends is run through the axle on each side of the central feed-slot, and these rods serve as stirrers of the zinc and effectually overcome the difficulty of the zinc packing. A pulley on the shaft running the tube-mill connects with a pulley on the axle of the feeder and operates the feeder.

The container, as designed, easily holds 112 lb. of zinc-dust, the amount usually packed in the sealed boxes in which it is marketed, and a cover can be provided for the feeder, thus preventing oxidation while in operation. Thinking that this device may be of use to the many cyanide operators throughout the country, I cheerfully offer it for their benefit.

A. W. MORRIS.

Mocorito, Sinaloa, December 31, 1911.

Cyanidation at Silverton

The Editor:

Sir—There appears in your issue of January 20, 1912, under the heading of 'Special Correspondence' from Silverton, Colorado, the following: "There is a great deal of agitation at present for cyanide plants, and it is probable that several will be erected during the coming season. Much of the agitation has been carried on by men inexperienced and poorly informed in the art of cyanidation, and many failures and much discouragement will no doubt result." I cannot help resenting this doleful statement and offer the following for your consideration.

As early as 1889, J. M. Callow, whose ability no one will doubt, conducted elaborate cyanide tests upon the ores of

Lee Lake basin and succeeded in demonstrating to his people beyond a doubt that the ores of the Grand View and Last Hopes properties were amenable to cyanide treatment. During the past season the Development Syndicate of which Root, Norton, and myself are members, conducted a series of tests on these ores, using compressed air for aeration and agitation and vacuum-filtration on 'Just' silicious filters. I do not claim to be an expert on cyanidation, although I have endeavored to keep in touch with its advancement, but I venture to say that Mr. Norton's experience and ability along this line is far better than average. Investigation of ores of this section, with regard to their amenability to cyanide treatment has been carried on by John T. Milliken, of the Golden Cycle G. M. Co., of Colorado Springs; Philip Argall, of the Independence mine of Victor; William H. Haldane, professor of metallurgy in the Colorado School of Mines; Louis Schaefer, a young engineer of exceptional ability, and others whose names are withheld for one reason or another, not to mention elaborate tests which have been made on the ores of a number of San Juan county properties and which have been unquestionably successful. It is among these people that much of the agitation for cyanide treatment of our ores has been carried on, and I challenge the allegation that such agitation is coupled with inexperience and poorly informed effort as the statement made in your esteemed journal would seem to indicate.

WARREN C. PROSSER.

Silverton, Colorado, January 28.

The Sherman Law

In an article on 'The Enforcement of the Anti-Trust Law' in the February *Century*, Mr. Wickersham, the Attorney General, states that discontent with the law and its enforcement by the present administration is not nearly so widespread as is popularly supposed. A few thoroughly discontented people are apt to make far more impression than do a host of people who are wholly satisfied with the same conditions which produce discontent on the part of others. It is a reasonable assumption that the majority of the people who are discontented with the Sherman law and with its enforcement are the stockholders and others interested in those corporations and combinations charged with its violation. The people who will most benefit from the enforcement of the law are the great army of consumers who have been purchasing the products of these corporations. It is certainly obvious that the number of consumers so benefited must far exceed the number of stockholders who may, in some degree, be injured. But even in the case of the stockholders, the injury to them is greatly exaggerated. The purpose of the law is not to destroy industries. Because the courts have not sought to destroy property, some extremists have uttered loud complaint, but that fortunately will not lead the courts to change their course.

DETAILS have recently been made public of a new method of making chilled rolls for sheet and tin-plate mills, in which the chilling is done by air-blast instead of by water. The chilling section of the mold is surrounded by a drum having a spiral internal fin. Air under pressure is fed into this drum, and, after circulating in a spiral course around the mold, is exhausted to the atmosphere. The mold is ribbed, radiator fashion, to facilitate cooling. The operator can control the cooling effect at will by manipulating a gate valve where the blast enters the mold, and a thermometer fixed in the flow of the blast as it leaves the drum indicates exactly how the cooling is proceeding. It is claimed that the process not only produces a perfectly even chill, but a surface is given to a sheet or tin plate roll which is practically the same as that given by the water-chilling process and without the risk of internal stresses in the metal. The time of cooling is absolutely within the power of the operator, so that the metal can be set rapidly to get the necessary polish for the face and then the body be cooled gradually to eliminate the casting stresses.

LOS ANGELES

MINING ENGINEERS OF SOUTHERN CALIFORNIA ORGANIZED.—

AFFILIATION WITH A. I. M. E. UNDER CONSIDERATION.

—LIBRARY AND READING-ROOM PLANNED.

As a result of the visit of the members of the American Institute of Mining Engineers on their way to the San Francisco meeting last October, an organization of the mining engineers of southern California has been formed here, and steps have been taken toward the establishment of a library and reading-room. Affiliation with the American Institute of Mining Engineers is a subject under discussion. An organization to accomplish what is planned would require dues, it is felt, of not less than two dollars per month, independent of those paid to the Institute. Some uncertainty exists as to whether a chapter of the A. I. M. E. would have the power to carry out the plans of the new body, as the provision that the rules may at any time be changed by the Council of the Institute without consulting the chapter is regarded as unfavorable to the plans under way here. Among the matters for particular investigation are, whether a chapter may make rules which would limit the controlling vote in its own meetings to professional men, and whether the Institute would allow the recognition, under the name of Patron, or similar title, of persons who by a substantial contribution of cash or books were prominent in establishing the proposed library. These matters have been referred to the Council of the Institute for an opinion.

At the organization meeting, held December 28, of which F. J. H. Merrill was elected chairman, the following resolution was passed:

"Resolved, That it is the sense of this meeting that an organization of the mining engineers of Southern California should be formed at once for the purpose of professional intercourse and the maintenance of a suitable reading-room and professional library."

This resolution, which was presented by C. Colcock Jones, was supplemented by another, also presented by Mr. Jones, which was passed, providing for the appointment by the chair of a committee on organization. This committee appointed includes F. J. H. Merrill, C. C. Jones, T. B. Comstock, and W. F. Staunton.

Among the speakers at the organization meeting were Mr. Jones, who spoke of the pressing demand for a technical library for mining engineers and who mentioned the advantage of occupying rooms in the same building with the Sierra Madre club; and G. E. Bailey, who emphasized the fact that since the fire of 1906, which destroyed the libraries in San Francisco, there has been no adequate collection of technical books in the state. Russ Avery, president of the Chamber of Mines and Oil, offered the use of the rooms of that organization, together with the use of its reading-room, and expressed the hope that an affiliation with that body might be effected. A. Del Mar stated that he favored the organization of the professional mining engineers and geologists of Los Angeles and vicinity, and the establishment of a reading-room and library, and that he believed the organization should be independent of all clubs and existing societies and associations. In reply the chairman stated that there had been no intention, by those interested, of affiliation with any city organization, and that the idea of having the rooms near the Sierra Madre club was merely for convenience and economy. H. V. Johnson spoke of his experience with Eastern technical organizations while associated with the United States Geological Survey at Washington. Julius Koebig favored the proposed organization for protection against unqualified men and promoters. L. D. Godshall favored the organization of a purely technical society, independent of existing bodies, but possibly affiliated with the A. I. M. E. Other speakers advocated the same ideas, excepting R. W. Hadden, who opposed affiliation with the Institute. W. R. Wharton said that E. A. Montgomery was unable to be present, but had

telephoned the offer of the board of directors of the Sierra Madre club of the use of the clubrooms at any time, and any other feasible coöperation. E. Call Brown was secretary of the meeting, which was held in the Sierra Madre clubrooms. Those present were: J. H. Atkin, Russ Avery, G. E. Bailey, E. Call Brown, A. B. Carpenter, T. B. Comstock, A. Del Mar, J. H. Farrell, D. B. Gemill, L. D. Godshall, R. W. Hadden, A. B. Hall, Lewis Hind, Harry R. Johnson, C. Colcock Jones, Julius Koebig, Carl O. Lindberg, C. R. McCollom, F. J. H. Merrill, Desaix B. Myers, J. N. Nevins, R. H. Norton, T. H. Oxnam, H. W. Squires, W. F. Staunton, A. M. Strong, R. A. Sullinger, G. M. Swindell, W. R. Wharton, W. H. Wiley, Calvert Wilson, and Fred L. Wilson.

JOHANNESBURG, TRANSVAAL

NOVEMBER PRODUCTION BREAKS RECORD.—REPORT FOR LEADING MINES.—NEW EAST RAND PRODUCER.

Although November was a short month the output of gold constituted another record, being for the whole of the Transvaal 749,729 oz. of a total value of £3,057,213. The Rand output itself was 691,462 oz. of a total value of £2,937,141, an increase of 13,539 oz. and £57,507 on the preceding month. With a similar increase for the month of December (and there should be no difficulty experienced in

RANDFONTEIN CENTRAL MILL.

obtaining such an increase, seeing that it commands an additional day for milling), the December Rand gold output ought to exceed for the first time a total value of three millions sterling. It has taken only five years to add a million sterling to the value of the monthly gold output of the Transvaal, but, according to the present labor outlook, it will take a much longer period to add the next million. On mining grounds, too, the next additional million on the Rand monthly output will be difficult to obtain, for most of the available mining ground on the Rand, within comparatively easy reach of the outcrop, is already under tribute, while several properties are on the point of being exhausted. The progress for the next five years will probably therefore be much slower. It may take ten years to add another million to the value of the monthly output of the Rand after the three-million value has been reached, not because the Rand does not contain the latent resources to continue its progress at the present rate, but because of the looming labor and legislative troubles, not to mention those inherent to very deep mining.

A fair proportion of the increase credited to the month of November was due to the results obtained at the Modder 'B,' a new producer of some promise on the Far East Rand, where, until quite lately, there have been nothing but disappointments, where to record the closing down of Cloverfield, Van Dyk, and Grootvlei properties does not give a good aspect to the future of that field. With the success attending the starting of the mills at Modder 'B' and Brakpan, the Far East Rand is looking better, and it is hoped that this improving aspect will not be in any way marred by the results of the new Wray-Arbuckle process now being introduced at the Benoni Consolidated Mines. The labor aspect is disquieting, but, nevertheless, the declared profits

for November were higher than for several months past.

The following are the twelve leading gold producers, with details of their stamps and tube-mills, at work, along with the tonnage treated and value of gold obtained during November. It may be noticed that these produced more than half of the total gold output of the Rand.

	Stamps.	Tube-mills	Tons.	Value.
Randfontein	775	23	204,534	£248,505
Crown Mines	620	19	140,200	246,445
East Rand Proprietary	820	25	168,853	219,578
Robinson	250	6	52,300	115,759
Goldenhuis Deep	420	7	63,020	90,719
Rose Deep	300	7	63,800	88,994
Simmer & Jack.....	320	7	66,500	85,745
Robinson Deep	210	5	49,350	82,763
New Modderfontein...	180	7	51,200	82,095
Nourse Mines	260	7	47,300	74,926
Village Main	220	5	38,687	74,454
Village Deep	180	6	48,700	69,387
Totals	4,555	124	994,444	£1,479,370

NEW YORK

COPPER SITUATION WEAKER.—RAY CONSOLIDATED AND CHINO TO MAKE APPEARANCE ON PARIS CURB.—SILVER MARKET.—GENERAL NOTES.

The close of the first month of the year appears to mark the wane of the much-talked-of revival in business and market activity, of which so much was made over the holiday season and during the first fortnight of January, while the two hundred and odd millions of dividend money just disbursed was seeking a permanent lodgment again. The boomlet, of which a good part was based on the improved conditions prevailing or supposed to prevail in the copper market, seems to be losing headway. There was a strong undertone of skepticism noticeable in the criticisms and comment on the situation at the time when the metal market was moved up so rapidly. It was said in more than one quarter that none of the unfavorable factors which created the business stagnation of the past year had been really and finally eliminated, and it was by no means plain to the average mind as to why general resumption of activity should be declared to be at hand. The present course of events seems rather to justify the position of the skeptical ones.

Wall Street has discussed the relations of 'big business' and politics, and operators have declared variously for a complete divorce on the one hand and for an indissoluble union on the other, with all shades of opinion occupying the middle ground. It seemed almost impossible to believe that any one topic could be so universally and perpetually discussed. In fact, it is quite plain that many of the disputants have so far become involved in discussion that all bearings are lost. To use a term of the Western cattle country, some one is needed to "turn the leaders and start the bunch to millin". The phraseology Wall Street probably would not understand, but it covers the situation.

In copper the strength has disappeared and prices are shrinking, even though it is anticipated that the Producers' report for January will show a further reduction in surplus stocks. Metal prices are lower, and copper can be purchased for a shade less than 14c., whereas it was predicted that a 15c. market would be established within a short time.

Foreign despatches quote the traders on the Paris Bourse as complaining somewhat bitterly that, believing fully in the predicted rise in copper metal and copper shares, they loaded up with Rio Tinto and are now facing substantial losses on the failure of hopes and predictions to materialize. Rio Tinto is one of the chief speculative issues on the Bourse, ranking in that regard as does Amalgamated in the New York markets. The French investor is the envy of all other nations and is regarded greedily by the large banking houses of other countries which have securi-

ties to distribute and know the importance of placing them as permanent investments. The French investor buys for income only, in small lots, and his investments are as permanent as he can make them. For some time there has been a strong effort to interest the French people in American securities, and through the Paris *Coulisse*, which is the Bourse's unlisted department or curb market, there have been distributed some very satisfactory amounts of Utah Copper. Ray Con. copper and Chino are to follow suit, and the shares will in a few days be traded in on the *Coulisse*. The two companies are not entirely new to the French public, as some good-sized blocks of bonds in each company were placed in France some months ago. Foreign bankers are undoubtedly taking greater notice of copper securities, especially of the new producers, than they have heretofore, partly on account of the new alignment of interests on this side and partly on account of the new war maps which are making in England and in Europe. It is now announced without attempt at concealment that the heavy exports of copper made during the past three months were for ammunition purposes, and in large part went to unusual points of destination.

The advance in silver, coupled with the possibilities of commercial awakening in China, is a cheering factor for many mining companies operating in Mexico, and would lead to some activity in properties and the formation of new companies to prospect and develop, if the new administration could but get its police department into effective action. The reports of brigandage and lawlessness are said to be exaggerated, but in any event are sufficient to prevent any new capital going into undeveloped or partly developed enterprises.

The bonds of the Inspiration Consolidated Copper Co. are being traded in on New York's curb market at a premium of 6 to 7%. The issue, which is for \$6,000,000, was underwritten by J. P. Morgan & Co. and was offered to stockholders of February 1 on a *pro rata* basis. Practically all of the stock of the old Inspiration company and the Live Oak company was turned in for exchange, only one or two insignificant lots being turned in for cash.

The United Verde suspended dividends because revenue is needed to complete the new smelting plant, and shipments from smelter to refinery are to be made hereafter by way of Galveston by rail and thence to New York by water. Transportation costs are cut materially by this new routing, but refinery returns are also delayed some fifteen days in transit.

The United Verde Extension, which has the habit of periodical reorganization, has just secured the consent of the shareholders for another financial plan which practically means a cutting in two of the present holders' interests and the granting of a working option to some larger copper people, whose identity has not yet been revealed. San Toy shareholders are mildly interested in an insurgent movement inaugurated by a committee of local stockholders. San Toy's annual report was in the mails during the current week, and each shareholder, in the same day's mail, received a letter from Chihuahua asking that all proxies be withheld until the new committee had time to communicate further. A little curiosity was aroused, inasmuch as there has been no particular complaint against the management of the San Toy or any dissatisfaction among the shareholders of any consequence. The company paid \$360,000 in dividends in 1911.

Cobalt Central was at one time one of the best engineered promotions among all of those supposed to be developing Canadian silver properties. This week the United States Marshal was sent out to make a levy on any property that could be found, and on his return he stated that he was "unable to find the company or any of its officers."

Stewart Mining, one of the Coeur d'Alene mines which is supposed to be controlled by the United Copper Co., has been active during the past week, and the shares have moved from 50c. to \$1.25. It is stated that some 110,000 shares were purchased at private sale at figures above the quoted market value, and that the purchasers have an option on some 300,000 shares additional. In some quarters it is intimated that the money derived from the sale

of this stock is to be used in paying off the floating debt of the United Copper Co. It is hardly to be expected, however, that F. Augustus Heinze, with any material part of \$110,000 in hand, would do anything so prosaic as to pay off the United Copper indebtedness, floating or sinking.

The Barnes-King Development Co.'s management is seeking for a new property in which to invest the treasury fund of the company and which can be equipped, if possible, in part at least, with the machinery on the old property. The company has something over a quarter of a million to purchase a new property if something suitable can be found.

SALT LAKE CITY, UTAH

PRODUCTION OF PHOSPHATE FERTILIZER MAY UTILIZE SULPHURIC ACID BY-PRODUCT OF SMELTERS.—BISMUTH ORE.

Several deals are pending in regard to the manufacture of fertilizer here, utilizing the phosphate ore from Utah, Idaho, and Wyoming, and the sulphuric acid which can be made as a by-product of the smelters. The importance of the phosphate as a fertilizer has not been recognized by many in this district, although there have been some who have been locating and buying phosphate deposits during recent years. Some of the larger Pacific Coast companies have been acquiring holdings in the Utah, Idaho, and Wyoming fields, but the mining has been done in a desultory way, and the rock has generally been shipped to California and Washington for treatment. Meanwhile the American, United States, and International smelters, operating in the Salt Lake and Tooele valleys, have been collecting the fume residues, but have not been utilizing the products for the manufacture of sulphuric acid. The position has been taken that the profit would be absorbed by the freight to markets. The smelters are now all making a study of phosphate conditions and markets, and it is expected that at least one contract will be closed soon whereby one of the smelters will begin the manufacture of sulphuric acid to supply a fertilizer plant which will be built in the neighborhood of Salt Lake City. The proposed fertilizer plant is backed by Salt Lake capitalists who are heavily interested in phosphates. They look first to the Coast for their market, but also expect to develop a demand for the production in the intermountain region and farther east. A deal of this kind will be important to the holders of phosphate deposits, to the farmers who want cheap fertilizers, and to the smelters who will find a new use for a by-product.

The less common minerals are attracting increased attention in Utah. Prospectors are now scouring the hills for phosphates, potash, and the rarer metals. The development of the alunite discovery near Marysville has led to a study of potash and its possibilities, and now various reports are coming in from different parts of the state about discoveries of phosphates and potash. Marysville is one of the latest to report a discovery of phosphate, in addition to the deposits of alunite there.

Frank L. and Clyde Wilson, who have long been operating in the Deep Creek district, in eastern Utah, claim they have made an important discovery of bismuth ore. They say that on the Wilson Consolidated property, near Hapah, they have opened up a 3-ft. vein of ore which will average 5 to 10% bismuth, while samples run as high as 47% bismuth and \$2.80 per ton in gold. A shipment of high grade is promised as soon as the roads open in the spring.

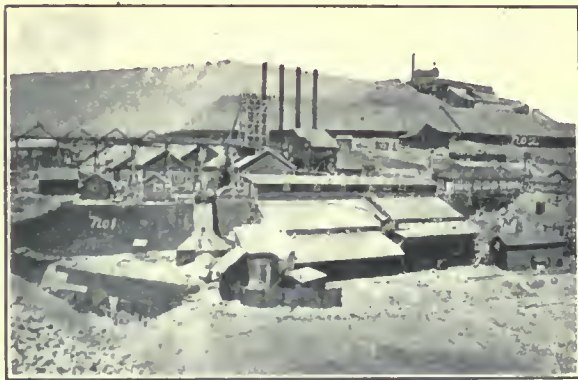

The Utah Consolidated is affected by the advance of copper more than many of the other properties, because a great deal of the ore which has been disclosed in recent developments is of so low a grade that it is close to the border line of profit. With copper higher in price, it is possible for the Utah Consolidated to ship an increased tonnage at a fair margin, and to make increased profits out of its higher grade. The shipments have been increased already from about 400 tons early in the year to close to 600 tons per day, and preparations are being made at the mine to increase shipments, without in any way slackening the prospecting.

CRIPPLE CREEK, COLORADO

DIMINISHING PRODUCTION OF LAST FEW YEARS.—EFFECT OF DRAINAGE ADIT.—DIVIDENDS OF COMPANIES IN DISTRICT.

The fortunes of Cripple Creek are being substantially retrieved by two important late developments, the advance in metallurgy and the completion of the deep drainage adit. Of these, the latter will probably have the more immediate effect.

The gold production of Cripple Creek has steadily declined from more than \$18,000,000 in 1900, to \$11,000,000 in 1910, and to \$10,500,000 in 1911. Contrary to general expectations, last year's output was half a million dollars below that of the preceding year. In the same period there was a steady increase in the tonnage of ore mined; but while the tonnage was growing the average value of the ore was diminishing. This is one cause of the decline in output, but in this situation there is a reason within a reason. This inner reason centres in the drainage of the district by co-operation, agitation for which began as far back as 1902. It was fully apparent to the operators at that time that adequate drainage was essential to continued productivity at a normal rate, and that the drainage could be effected only by united efforts. This agitation culminated in definite plans for another deep drainage adit late in 1906, and on May 11, 1907, work on the Roosevelt adit was started. Since

PORTLAND MINES.

that date few of the larger properties have made any attempt to continue production from their lower or submerged levels, on account of the heavy pumping expense necessary. It was deemed better policy to await the completion of the adit. Consequently for seven years the operators have with few exceptions confined their operations to ground largely worked over. The upper levels were still capable of yielding large tonnages of ore, though of a much lower average grade. It was clear that this must temporarily result in a diminished production, but now the operators see the wisdom of their policy of voluntary curtailment.

Cripple Creek has reached its turning point. Late in 1911 the benefits of the deep drainage adit began to show. The water courses cut on November 15, both in the main heading and the Fuller cross-cut to the C. K. & N. vein in El Paso ground, suddenly threw into the adit a volume of water which flowed for several days at the rate of 20,000 gal. per minute. This at once affected the entire district, with the exception of the Vindicator and Golden Cycle properties to the east, which lie in a separate drainage basin, cut off from the remainder of the camp by an impervious dike. The net results of the drainage enterprise to date are as follows: The El Paso mine is dry down to the drainage adit level, which is 1338 ft. below the collar of its shaft; the Gold Dollar and Mary McKinney are practically drained to their lowest workings; the Portland has recovered its 1500-ft. level and the Independence its 1000-ft. station; the Elkton, Strong, Granite, and Gold Coin will be drained to their lowest levels within a short time; the Cresson has recovered one level. The water level has receded an average of 80 ft. for the entire district; the

average rate of recession at present is $8\frac{1}{2}$ ft. per month.

In point of dividends paid by Cripple Creek mines, the year 1911 was exceptional. The following dividends were paid during the year:

Golden Cycle	\$1,410,000
Portland	240,000
Elkton	225,000
Vindicator	180,000
Stratton's Independence	120,000
Gold King	80,000
El Paso	61,250
Jerry Johnson	50,000
Anraria-Forest Queen	36,000
Maggie	26,000
Modoc	5,000
Acacia	7,200
Granite	16,500
Stratton's C. C. M. & D.	50,000
Cresson (estimated)	120,000
Lessees and private properties.....	250,000

Total for year \$3,006,950

Total for 1910..... 1,479,399

The total number of tons of ore mined in Cripple Creek during the year, including tailing re-treated (13,850 tons) and dump ore, was 903,596 tons, of which the gross bullion value was \$15,622,436, as given in the reports of the mills and smelters. The smelters handled only 48,020 tons of the total output.

LONDON

LE ROI NO 2. TO INCREASE RESERVES AND DECREASE DIVIDENDS.—G. H. STANLEY'S PLAN FOR RE-TREATING RAND DUMPS.

The directors of the Le Roi No. 2 company have decided to restrict the already small dividends and to place as much as possible to reserve. The reason for this policy is not quite clear, but as it was promulgated at the instance of the largest shareholders, nobody can complain. For seven years the company has been existing in a hand-to-mouth sort of way, and, considering the original history of its formation, the results reflect great credit on the engineers. At the present juncture it is timely to give a résumé of past events and of the latest year's work. The company was floated in 1900 by the late Whitaker Wright for the purpose of working the Josie, Poorman, and adjoining copper-gold properties at Rossland, British Columbia. Subsequently the management was placed in the hands of Alexander Hill & Stewart, and their representative, Ernest Levy, has done excellent work under circumstances which were far from promising. During the year ended September 30 last, development and prospecting by means of the diamond-drill have continued to disclose new veins and shoots, but the ore reserve is less than formerly as regards quantity, though not in quality. The total footage of development work was 5577, and 14,932 ft. of diamond-drilling was done. The most important recent discoveries have been a new vein called the Holywell, and a new shoot in the North Annie vein. During the year, 67,033 tons of ore was raised. Of this, 22,414 tons was discarded as waste, 27,098 tons was shipped to the smelter, and 17,521 tons concentrated. The shipping ore was estimated to contain 1.6% copper, 16.7 dwt. gold, and 0.7 oz. silver per ton, having a gross value of \$21 per ton, and net value, after deducting smelting charges, of \$15.20 per ton. The concentrating ore averaged 0.5% copper, 2.8 dwt. gold, and 0.2 oz. silver per ton, and 1589 tons of concentrate was produced, which averaged 1.29% copper, 1.425 oz. gold, and 0.75 oz. silver per ton, with a gross value of \$32 per ton, and a net value, after payment of smelter charges, of \$25.50. The receipts for ore and concentrate were £84,806, and other receipts brought the income for the year to £91,474. The divisible profit was £30,176, which, added to the balance brought forward, made a disposable amount of £74,181. Out of this, £1700 went as directors' share of profits and £36,000 as dividend, being the same

as during the year before. Owing to the inflated capital, £600,000, a legacy from the previous controllers, the rate of dividend seems unduly small. Many attempts have been made to reduce this nominal capital, but the directors have not seen fit to do so. The par value of the shares is £5, and it would be only reasonable to reduce it to £1, and so make the capitalization somewhere near the value of the assets. In future the yearly dividend is to be restricted to 2s. per £5 share instead of 6s. as paid during the last two years. Presumably other properties are in view.

It is rarely that the question of re-treatment of old Rand dumps comes up for discussion. Yet there are millions of dollars worth of gold locked up in them. The content may be only from \$1 to \$2 per ton, but the total tonnage must be nearly 100 million of material thrown aside before the modern practice of tube-milling and agitation of slime was adopted. The problem of re-treatment of the accumulated tailing has often been considered, but no serious effort has ever been made to carry the plan into effect, it being generally supposed that the question could be postponed until a later date when the mines themselves began to give a decreased output. The new policy of using the tailing as filling for the exhausted stopes has caused those interested in the metallurgical problem to press matters forward, for it is obvious that if the tailing is sent underground again, its gold will be lost forever. It is clearly recognized that the content of the tailing dumps varies widely, as also does the fineness or coarseness of the constituent particles and the relative amount of pyritic material present. Many people who have considered re-treating the dumps have been deterred by this irregularity and the consequent difficulty of separating the material that requires regrinding. A new classifier invented by G. H. Stanley, professor of metallurgy in the South African School of Mines, removes this difficulty. It has been tried experimentally at the Robinson mine, under the supervision of W. Laurie Hamilton, and the results have been tested by A. F. Crosse. Mr. Hamilton estimates that there is 70 million tons of sandy tailing, left in the days before the advent of the tube-mill, and that the gold in it amounts to from 1 to $1\frac{1}{2}$ dwt. per ton. The Stanley machine is a combination of a hydraulic classifier and a screen, and is designed to keep the largest sizes together, irrespective of their specific gravity. Much of the coarse material is pyritic and settles easily, but the lighter parts are apt to pass over with the fine. In order to prevent this, a screen is interposed which collects the coarse light particles, and at intervals returns them to the heavy coarse material. By this arrangement the sand of the dumps is separated into three classes: (1) concentrate consisting of +60 material together with the pyrite; (2) fine, consisting of -60 material, and (3) slime. Of these three divisions, the concentrate contains from 40 to 65% of the total gold, and the fine 40 to 45%, while the slime is of less importance, being only 3 to 5% of the total weight of dump material. In the trials of the Robinson dump the following figures were obtained: Content of dump, 1.13 dwt.; content of concentrate, 1.55 dwt.; content of fine, 0.68 dwt.; content of slime, 1.85 dwt. The concentrate was reground, and by cyanidation and agitation gave an extraction of 80%. The fine did not require regrinding, and gave 67% extraction. The slime gave 90% extraction. It is calculated that the average extraction will be 75%, with a minimum of time occupied in the process. The cost of treatment per ton is estimated at 6d. for classification and transport, and 7½d. for regrinding, and 1s. 3d. for cyaniding, being a total over the whole amount treated of 2s. per ton. If the dump material is treated immediately before its delivery for stope-filling purposes, the cost of handling will be reduced. The probability is that a profit of 1s. 6d. per ton can be made on this particular dump, without including the outlay on plant or cost of administration.

According to statements made at the recent company meeting of the Atbasar Copper Fields, Ltd., the report of R. Gilman Brown shows a reserve of 389,000 tons of ore containing copper to the estimated value of £3,000,000.

General Mining News

ALASKA

PRINCE WILLIAM SOUND

What is regarded by some as an indication that the moraine on which Valdez is built would be profitable for dredging, was the pumping of gold-bearing sand at the Exchange building in that city. The water on being pumped is strained through a sieve. An accumulation of sand in the sieve equivalent to a quarter pan yielded about 7c. in gold.

A townsite has been staked by miners at the mouth of the Aniak river, a tributary to the Kuskokwim, and the Northern Commercial Co. has ordered logs for the construction of permanent buildings. A population of 500 is expected before the end of winter, as the gravel is unusually rich.

ARIZONA

COCHISE COUNTY

Reports from Bisbee state that Henry Brender, of that city, recently arranged for teams to haul ore from the Beckler property to the railroad station of Rodeo, where it will be shipped to the Copper Queen smelter. The ore is said to assay about \$100 per ton. Concentration ore from the property will be delivered to the new concentrator of the Paradise M. & M. Company.

GILA COUNTY

(Special Correspondence.)—The Hardinge mills for the sixth unit of the Miami concentrator have not yet arrived. No announcement has yet been made as to when the construction of the 7500-ton mill by the Inspiration Con. Copper Co. will be started. Work is progressing on the water-supply dam, and J. M. Callow is experimenting. Underground work has not yet been started. At the Live Oak, development of the mine in a small way continues. A 15 by 20 double-drum hoist has been purchased from the Old Dominion company and will be erected at No. 2 shaft, which will be enlarged to three compartments. According to present intentions of the management, future increase of ore reserves will be accomplished by underground work rather than by churn-drilling. Churn-drill hole No. 2 of the Southwestern Miami Development Co. is now over 500 ft. deep. Ore is expected at about 900 ft. Drilling continues steadily on the Barney group, which is under option to the Lewisolms. A hole was recently started at the bottom of the 400-ft. shaft about 3000 ft. west of the Live Oak west-end line. The hole is in schist.

Six men are employed in the development of the New State group of 33 claims on lower Pinto creek, 15 miles west of Globe. On the Republic claim, a trench was started on the Duquesne vein, and is reported to have disclosed, near the surface, one to three feet of shipping ore containing gold, silver, and copper. The ore occurs in limestone. There are 20 tons of ore on the dump, and preparations are being made to ship. Smelter returns on a carload of ore recently shipped to the El Paso smelter from the Duquesne mine, 15 miles west of Globe, gave credit for 39 tons of ore assaying 0.76 oz. gold, 11.6% lead, 17.8% iron, and 33% insoluble. The net returns above freight and smelter charges amounted to about \$18 per ton. A carload of lead-silver ore has just been shipped to the El Paso smelter from the Copper & Silver Zone group, two miles east of Globe, which is owned by H. W. Clark and associates and is being worked by several lessees. Shipments from these claims have been running 80 to 100 oz. in silver. The cross-cut north, from the McGraw shaft, on the 12th level at the Superior & Boston, has cut a vein reported to be 4 ft. wide and to carry copper ore of a good smelting grade. The Cracker Jim shaft has been unwatered and a 25-hp. gasoline hoist has been erected. The shaft is 125 ft. deep, and sinking will be resumed this

week. It is proposed to cross-cut at 200 ft. to the Maverick vein, from which some high-grade copper ore has been mined.

(Globe, February 2.)

MARICOPA COUNTY

A compressor and air drills have been delivered at the Carney property, near Mesa. It is believed that the adit will intersect the orebody within the next 50 days. Thomas Frazier is superintendent of the property.

YAVAPAI COUNTY

Pitchblende has been discovered in a mine owned by W. H. Slaughter, near Columbia. It is rumored that operation on a large scale will be started at the property of the Ohio Mines Co., sometimes known as the Little Jessie, near Chaparral. Unusually rich gold ore recently was discovered in an old mine on Lynx creek, near Walker, according to A. J. Doran and J. L. Batchelder, of Prescott.

YUMA COUNTY

George V. Bell is reported to have discovered rich deposits in the desert, near Quartzite. The old Fortuna property, which has been idle for ten years, has been dismantled. James Maxey secured what was left of the machinery for use in the Colorado river control work near Pascualitos, a station on the Southern Pacific railroad.

CALIFORNIA

AMADOR COUNTY

(Telegraphic Correspondence.)—The collapse of shaft timbers in the Bunker Hill mine, two miles north of Sutter Creek, caused a cave-in Wednesday afternoon which imprisoned 63 miners. The telephone wires and air-pipes were not injured, and the men were rescued Thursday be-

EUREKA MINES, AMADOR COUNTY.

fore noon. The United States Bureau of Mines offered assistance, and F. L. Lowell is on the way from San Francisco to represent the Bureau.

(Amador City, February 8.)

(Special Correspondence.)—Among the companies whose reorganization marks the revival of Mother Lode development, the Con. Amador M. Co., a reorganization of the Amador company, owning the Eureka mine, has aroused unusual interest among old-time mining men. The new company will operate the property on a large scale. E. H. R. Green, son of E. H. Green, one of the early capitalists, is president of the new company; J. B. Mackie, associated with pioneer-day development, is vice president; A. L. Black, cashier of the Bank of California, will represent the old English stockholders, while other members of the board of directors will be James R. Cashman, an associate of Andrew B. McCreery, together with Frank Seed, and R. B. Symington, who was earlier associated with D. O. Mills, Elviza Hayward, and P. B. Cornwall, as consulting engineer. The report of J. Ross Browne, in 1868, referred to the property as one of the most valuable gold mines in California. Development was started in 1852, and in that year a 10-stamp mill was erected. The property of the present company includes two old claims, the Eureka and the Badger, which Mr. Hayward consolidated in 1859.

Within the first 500 ft. of the surface the yield did not exceed \$11 per ton of ore, and it is said in the report that for the first 200 ft. so much difficulty was experienced in keeping the mill going that the laborers worked 'on trust' until the property paid expenses. R. W. Raymond, then special commissioner of mining statistics, in 1869 reported on the property, which was variously known as the Amador, Eureka, and Hayward, but which then was owned by the Amador company. The total yield for October 1867 to October 1868, inclusive, was \$566,946, according to the report, in which Dr. Raymond called attention to the fact that while the property yielded a revenue of \$300,000 per year, the company paid for it only \$750,000 cash, and cited that as a good example of the actual cash value of a mine in regard to the profits. The property was examined for the company by Messrs. Ashburner and Janin. The mine has been idle for 25 years. The Amador M. Co. was organized February 5, 1872, exactly 40 years before the present reorganization. Among the men first associated with the company were David D. Colton, Milton S. Lathan, E. H. Green, and Mark L. MacDonald.

Sutter Creek, February 8.

The Keystone Mines Co. is repairing the shaft of the Keystone mine, near Amador City, which it was organized to take over from the Consolidated Mines Co. It is reported that the shaft will be sunk to greater depth and that cross-cutting will be started in the near future. C. R. Downs is superintendent of the property.

INYO COUNTY

The Skidoo Mines Co. in December made a total production of \$14,336, of which \$13,240 was bullion and the rest concentrate. Operation and development expenses amounted to \$8263, leaving a net profit for the month of \$6074. The cyanide plant has been closed for the winter.

Jim Butler has accepted the presidency of the Prospectors' Alliance of America, which was organized at Bishop a short time ago. Other officers are: vice-president, L. C. Hall; secretary, C. E. Kunze; treasurer, W. M. Snider; directors, T. L. Oddie, Governor of Nevada, A. H. Swallow, G. W. Leidy, Eugene Grutt of Rawhide, and C. E. Kunze. Honorary memberships were conferred on William E. Borah, U. S. Senator from Idaho; J. E. Raker, U. S. Representative from First district, California; and Charles E. Fuller, of Illinois. By-laws and articles of incorporation were adopted. The membership fee is one dollar and the annual dues two dollars. The meetings will be held annually, and special sessions may be called, a quorum to consist of 25, including proxies. At the meeting it was reported that about 200 had signed the membership list, while 560 had signified their intention of joining. They all were elected members at the meeting.

LOS ANGELES COUNTY

The election of the Chamber of Mines and Oil, held here recently, resulted as follows: President, Russ Avery; first vice-president, S. E. Varnilyea; second vice-president, W. C. Kennedy; treasurer, D. F. McTiary; chairman of committee on building and expositions, Henry Blumenberg, Jr.; on commercial and mercantile affairs, M. W. Everhardy; on engineering and economic geology, Harry R. Johnson; on hotels and entertainment, E. A. Montgomery; on finance and auditing, Calvert Wilson; on grievances, Joseph A. Lewis; on laws and statistics, Theodore Martin; on library and publications, F. J. H. Merrill; on manufacturing, S. G. Bailie; on membership, Harry S. Jones; on mineral and geological exhibit, J. Nelson Nevius; on mines and mining, W. H. Aldridge; on petroleum, W. W. Orentt; on publicity, Desaix B. Myers; on reports and certificates, R. King; on transportation, H. D. MacKinnon.

NEVADA COUNTY

The mill and all other buildings, excepting the superintendent's cottage, on the W. Y. O. D. property were destroyed by fire on January 31. The men underground were safely removed through the Pennsylvania workings. The mill machinery was being removed to the Pennsylvania property, to enlarge the mill there, and the loss was less

than otherwise would have been the case. The Empire M. Co. recently acquired both the W. Y. O. D. and Pennsylvania properties from the Pennsylvania M. Co., and planned it is reported, to use the W. Y. O. D. shaft for pumping only. The W. Y. O. D. property originally was owned by Joseph Weisbein and associates.

SAN BERNARDINO COUNTY

It is rumored that operation is to be resumed at the Big Chief M. Co.'s property at Hart. F. E. Browne is in charge of the mine.

SAN DIEGO COUNTY

A prospector named Lee Morris is reported to have discovered a vein assaying \$60 to \$100 per ton in the hills east of Campo, 55 miles from San Diego.

SIERRA COUNTY

Mrs. Julia K. Davis, of Downieville, is reported to have picked up a nugget valued at \$280 near the north fork of the Yuba river, about four miles north of Downieville.

The North Star Mines Co. has reopened the drift on the 1000-ft. level, which had caved in. The drift is now in 1500 ft. from the shaft, and will be continued into new ground. Pumping was resumed a short while ago and will be maintained until the mine is drained, says a recent report.

TUOLUMNE COUNTY

(Special Correspondence.)—The United States S. & R. Co. has secured a good bond on the Santa Ysabel mine, which adjoins the App on the south, and is negotiating, it is said, for the purchase of the Dutch and other properties in that vicinity. The transfer of the App and Rawhide mines by W. A. Nevills to the above-named company has not yet been made, the delay being occasioned by the making out of abstracts of title, but the deeds of conveyance will in all probability be signed and delivered within a few days. A new shaft is being sunk in a rich shoot of ore at the property owned by H. V. Pullen and Ed Burley, in the Basin district. The best ore, which assays about \$80 per ton, will be sent to the Selby works in the spring.

The company operating the Carlotta mine, near Tuolumne, has found a 2-ft. vein of rich ore in the south drift from the Carlotta shaft. The mill was started this week. The new 10-stamp mill at the Gem mine, operated by J. M. Wulzen, is making its initial run on good-grade ore. The Bonanza mine at Sonora, under bond to Los Angeles men, has been unwatered to the depth of 200 ft., and prospecting begun at 180 ft. Construction of a cyanide plant at Soulsbyville to treat the tailing of the Soulsby mine purchased from the Bagdad-Chase company by C. J. Sullivan and Frank Thomasson has been completed. The Sugarman pocket mine, on Bald mountain, northeast of Sonora, from which many thousands of dollars in gold has been taken, is being worked by Charles Smith and Robert Watson. The addition of 20 stamps to the Dutch mill will be completed about April 1. The Yankee Hill M. Co., which recently secured a large tract of land in the vicinity of Columbia, will begin prospecting with a drill for gold-bearing gravel within a few days. The Golden Dawn, near Soulsbyville, which is being worked by Nicholls brothers and Thomas Webster, is showing encouraging prospects, some of the ore being good enough for sacking and shipping. The Stanislaus M. Co., organized under the laws of California, filed articles of incorporation in this county on January 31. The capital stock is \$400,000, with shares at \$1 each, and the directors are V. D. Knupp, N. M. Ball, W. B. Phillips, E. E. Graham, and E. R. Abadie, all of Porterville. The company is actively operating the If I Can mine, near Mt. Pass. A mill and other surface improvements have recently been completed on the property.

Tuolumne, February 3.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—A 7-ft. orebody has been found on the foot-wall of the Gem vein at the 2000-ft. level that mills \$32.19 in gold and silver. Von Tilborg & Co. are operating under lease. James Cousins, manager

of the New Era mine at Freeland, has started shipments of smelting ore. The 60-ton mill is running on one 12-hr. shift. The McKelvey mill, in the west part of town, has again been brought into commission. The Hudson mill is now treating a large amount of custom ore, and \$3 ore is being handled at a profit. A. H. Roller is manager of the mill.

Idaho Springs, February 2.

SAN JUAN COUNTY

Otto Mears has secured a lease and bond on the Gold Prince mine and mill at Animas Forks.

TELLER COUNTY (CRIPPLE CREEK)

The El Paso Con. Gold M. Co. in 1911 shipped about 36,000 tons of ore, of which 18,700 tons was mined by lessees from the upper levels.

Fred Johnson and associates of Cripple Creek, lessees on the Pride of Cripple Creek property, have discovered ore said to assay as high as 40 oz. gold per ton on the 600-ft. level, north of the shaft. Due to the large amount of dead-work, the January output of the Forest Queen mine, Iron-clad hill, will not exceed 450 tons of ore. Hemby & Anderson, operating the Wild Horse, Silver Tip, and Ramona claims, Bull hill, are shipping about three cars per month of ore reported to assay \$75 to \$100 per ton.

The Vindicator Con. Gold M. Co. in 1911 made a net profit of \$238,804, and with the dividend paid January 28, amounting to \$45,000, has disbursed in dividends a total of \$2,452,000. The company during the year shipped 19,232 tons of ore valued at \$647,710, leaving a profit of \$529,349 after freight and treatment charges were paid. Lessees shipped 11,001 tons of ore valued at \$182,612, on which the net profit was \$121,693. F. L. Sigel is president and general manager for the company.

At a depth of 100 ft. on the Emma Abbott claim, owned by the Lady Campbell Gold M. Co., on the east slope of Tenderfoot hill, a 6-in. vein of ore assaying \$520 per ton was found recently, state advices from Cripple Creek. The claim is leased to F. J. Fitzmorris, of Kansas, and Peter Timmons, August Bay, and H. Dailey, of Cripple Creek.

A \$2500 gold brick was taken January 30 from the Kavanagh mill, the brick representing the clean-up for the month. During the month 1200 tons of ore was treated, the ore averaging \$2.60 per ton.

MONTANA

FLATHEAD COUNTY

(Special Correspondence.)—The engineers who have been at work at Kootenai falls for the past month have completed their examinations of the power-site there and have returned to New York to prepare their report on the plan to use these falls for obtaining power for the Coeur d'Alene mines and various cities, including Spokane. The Kootenai Power Construction Co. is the corporation organized by Joseph A. Coram of Boston to develop the power.

Libby, February 5.

LINCOLN COUNTY

(Special Correspondence.)—H. L. Wilson, foreman of the Snowshoe mine, recently stated that shaft-sinking has been discontinued at the mine and a station is now being ent at the bottom. The shaft is down 600 ft. A drift will be run in on the ore vein, which it is thought is not over 15 ft. from the bottom of the shaft.

Libby, February 5.

NEVADA

CHURCHILL COUNTY

H. J. Hoover, lessee on the Queen property near Wonder, has started development, which for the present will be confined to the 100-ft. level. The whim used in sinking to the 100-ft. level will be used, but later, when shaft-sinking is resumed, a hoist will be secured.

ESMERALDA COUNTY

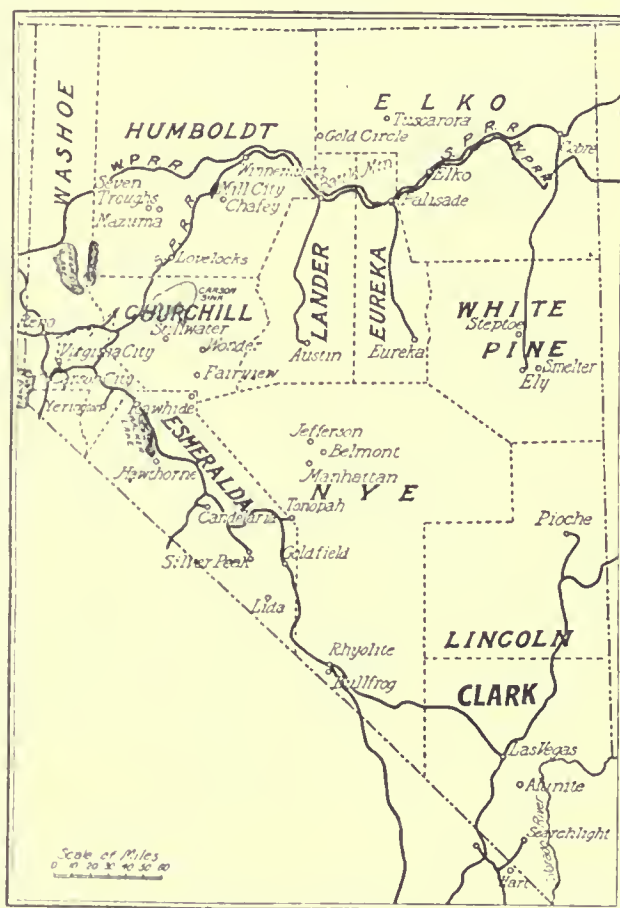

W. J. and R. F. Tobin have regained control of the Pioneer Con. Mines Co. They recently stated that shipments will be started in the near future. J. R. Bryan is manager for the company. The official report for 1911

states that the company has no debts, and has a balance of \$29,472 in the bank. During the year the company acquired the properties of the Bullfrog Pioneer Gold Mines Co., the Bullfrog Valley View M. Co., and the Gold Hills M. & M. Co. Operation on the company account started last June.

The Nevada Eagles M. Co. has about 40 tons of second-grade ore ready for shipment. It is reported that next month the force will be increased, and that plans for a mill are being made.

LANDER COUNTY

(Special Correspondence.)—Salt Lake capitalists, represented by W. J. Bowring and George Arbogast, have taken a lease and bond on the Austin Central group. Developments will commence about February 15, with work conducted from two points. The Maricopa Mines Co. reports a large tonnage of available milling ore. The Whitlatch

NEVADA.

Consolidated is sinking a shaft to prospect a fissure. It is possible the work may determine the extensions of the Silver Chamber, Snow Flake, and other veins. The Gold Basin G. M. Co. has been formed to operate in the Gold Basin district, 45 miles southwest of Austin. The company is organized under the laws of Utah, with a capitalization of \$1,000,000. The company owns 13 claims in the district with a prospect shaft 100 ft. deep. Frank B. Cook is president, Reuben May vice president, and Shand Smith secretary-treasurer of the company.

Austin, February 2.

NYE COUNTY

(Special Correspondence.)—A conservative estimate places the 1911 output of Manhattan at \$1,000,000. Of this amount, \$700,000 came from the quartz mines and \$300,000 from placers. Of the total quartz yield the Big Four produced about \$400,000. Rumors concerning the Big Four are rife, the latest being that the company plans building a new mill. An abundance of water is available, Manhattan being signally favored in this respect. The heavy flow of water on the 400-ft. level of the Big Four has forced the lessees to concentrate their work on the 300-

ft. level. The company reports a large quantity of milling ore developed, which can be profitably treated with milling facilities convenient. The orebody near the 200-ft. level in the White Caps is understood to range from 6 to 15 ft. wide, with a large portion running \$40 to \$103 per ton. On the Manhattan Consolidated the Steffner lease has opened a large vein of \$20 ore at a depth of 200 ft. The Mineral Hills Consolidated has proved its vein to a depth of 250 ft. The adit is going ahead steadily to intersect the vein at greater depth. On the Dexter, Union No. 2, and other claims the lessees report improving conditions. About 50 leases are active, with about 25 producing. All indications favor a marked increase in the gold yield for the present year. The Tobin brothers, of Denver, have resumed charge of the Pioneer Consolidated group, in the Bullfrog district, and preliminary work has started. Shipments will commence within a few weeks, according to statements of the owners. The property has lain idle for three years, owing to dissensions among the stockholders. It is rumored that attempts are being made to resume activities at the Mayflower Consolidated and Homestake King, two former Bullfrog producers. The Round Mountain M. Co. is treating 200 tons of ore per day. The ore is said to assay on the average \$6, with total mining and milling costs of \$4.10 per ton.

Manhattan, February 1.

It is reported that Weir Bros. & Co. of New York have underwritten 100,000 shares of the Halifax Tonopah M. Co., which has four patented claims, amounting to 81 acres, adjoining on the east the Tonopah Belmont property. The company is said to be expending about \$10,000 per month in development.

The Tonopah Midway M. Co. in 1911 shipped 2035 tons of ore, valued at \$65,699, and having a net value of \$22 per ton. Disbursements for the year amounted to \$64,000, of which \$34,606 was for labor. Receipts were \$88,048, of which \$47,527 was from ore sales, \$5000 from the sale of a fraction of the property, while there was a cash balance in the bank of \$35,520.

David D. Sullivan, says a Tonopah report, one of the syndicate which has an option on the Millett-Albion group of claims at Millett, is making plans for building a mill on the property. A test shipment of ore will be made soon to the Selby smelter to determine what process will be used. It is reported that a company, to be known as the Smoky Valley Gold Mining Co., will be organized, as a close corporation, to operate the property.

WHITE PINE COUNTY

The unwatering of the Giroux shaft is said to be going forward with greater rapidity than has been accomplished heretofore. The big pumps on the 1200-ft. level were put in commission last week, and the damage done to the shaft by the fire of August 23 has been repaired from the 1200-ft. level to the surface and the shaft is in good working condition. The foundation for a twin set of boilers for the Morris shaft has been completed.

WASHINGTON

PACIFIC COUNTY

Press despatches state that there was a rush toward the vicinity of South Bend on account of recent gold discoveries. One party of about 50 goldseekers came into conflict with the civil authorities through their occupation of part of the Ellsworth ranch.

SPOKANE COUNTY

Officials of the American Mining Congress will be formally advised in a few days that a fund of \$5000 has been subscribed and guaranteed by operators and business men of Spokane for the 1912 convention, which will meet the last week in November or early in December.

The Spokane Mining Men's club adopted the following resolution at the last meeting: "That while we favor equitable, reciprocal trade relations, we are unalterably opposed to the reduction of the tariff on lead and zinc as proposed by the Underwood bill now pending in Congress." W. W. Gifford, secretary of the club, says that though the club adopted a resolution on December 7 in regard to reciprocal

relations between the United States and Canada upon lead and zinc, it did not desire removal of the tariff on these metals.

CANADA

BRITISH COLUMBIA

The Windemere district, at the head of the Columbia river, will be benefited by the Kootenai Central railway, financed by London capital, which is to be completed from Fort Steel to Cranbrook early next September. The running time between Windemere and Spokane will be cut to 10 hours. At present it is three days by stage, thence six hours by rail. The mines have been idle for the last eight years, awaiting transportation.

A. Erskine Smith, president of the Red Cliff M. Co., Portland Canal district, it is rumored, will arrange for the construction of a mill for the company.

An analysis by the Canadian Department of Mines, of which Eugene Haanel is director, of a 4-oz. sample of black sand concentrate sent by Gilbert Blair, secretary for the British Columbia Platinum Co., Ltd., showed the following content: platinum, 521.57 oz.; osmiridium, 58.82 oz.; gold, 75.82 oz., and a small undetermined quantity of silver per ton. The concentrate was obtained, it is reported, from $1\frac{1}{2}$ to 2 cu. yd. of river sand and gravel from the company's property on Tulameen river, Similkameen district.

ONTARIO

The Wettlaufer Lorraine company in 1911 shipped 925,017 oz. silver. The positive ore reserve is estimated to contain 1,003,000 oz. silver. About 2180 ft. of development work was done, according to the report of H. Lindsley, general manager for the company. Total receipts from the sale of ore amounted to \$481,368. Production, development, administrative and general expenses, and depreciation amounted to \$167,977. A total of \$212,488 has been paid in dividends. The surplus at the end of the year was \$100,902, against \$121,908 the previous year. The net profit for the year was \$13,390.

MEXICO

CHIHUAHUA

(Special Correspondence.)—Serious disturbances have occurred in this state. All stores in Juarez have been looted, and one of the largest warehouses in the city, belonging to Messrs. Ketelsen & Degetau, was completely destroyed, with a loss of some \$250,000.

Juarez, February 5.

Operation of both mine and mill at the Calera M. Co.'s property, five miles from the San Isidro station, has been resumed. Frank Kyle is general manager for the company.

In the Parral district, work will be resumed soon in the Guadalupe mine, owned by Vincente Visconti. In the same district the Tepozan Gold Mines, Ltd., has been organized to operate the Tepozan mine, and later on the company is to erect a cyanide mill, according to a recent report. John F. Johnston is general manager for the company.

Paul Ginther, of Santa Rosalia, recently stated that he had 3000 claims in this state under option, most of which will be purchased. He will resume operation in the near future at the El Cerro de las Campanas and the El Siglo Veinte properties, in the Naica district, which were closed last year on account of the political disturbances.

SONORA

(Special Correspondence.)—Things seem to be unsettled again in Mexico and peace far away. There is practically no organized government in this state, there being four leaders, all of whom are striving to obtain supreme power. If the United States Government does not intervene, it is anticipated that these conditions will not improve in Mexico for some time, and if it does intervene, many are afraid of serious trouble, at least for several weeks.

Sonora, February 5.

PHILIPPINE ISLANDS

(Special Correspondence.)—The Paracale dredging field, after various delays, is to be financed in Melbourne. The

area taken over by the syndicate comprises about 800 acres of the choicest ground, including the 300 acres of the old Paracale Gold Dredging Company.

The ground averages about 30c. throughout the field, and the gold-bearing sand is about 36 ft. deep. The new company is capitalized at £300,000, in £1 shares. The stock has been subscribed by a small group of Australian capitalists. The contract calls for dredges to handle at least 80,000 cu. yd. of sand per month.

Manila, January 20.

Among the Copper Mines

CONSOLIDATION of the Ray Central Copper M. Co. and the Ray Con. Co. was announced by telegraphic advices from New York Thursday. This merger has long been in contemplation and is clearly in the interest of economy in operation, as the properties are adjacent and but parts of one orebody. According to a report made by Weed & Probert last year, the Ray Central had 5,020,000 tons of actual and 1,420,000 of probable ore, with an average assay value of 2.15% copper. Estimating on the basis of a production of 1000 tons per day, the probable cost was placed at \$2.97 per ton, equivalent to 10.38c. per pound of copper. The larger daily production possible as a result of the consolidation should reduce this figure.

THE OLD DOMINION properties at Globe, Arizona, were discussed interestingly recently by Dr. James Douglas, who is quoted as follows: "The company's output in 1911 was about 25,000,000 lb. of copper, practically all of which came from the Old Dominion and United Globe mines, as very little custom ore was treated during the year. The remarkable feature of the development during the past two years is the depth to which the secondary enrichment extended, and the size of the orebodies at a depth of even 1600 ft. from the surface. At the Old Dominion, as elsewhere, the increased quantity of concentrating and the decreased quantity of lump ore, points to modifications in the company's smelting methods for the future."

THE CANANEA DULUTH COMPANY, says the *Boston News Bureau* of January 24, has been dissolved and its assets, consisting chiefly of the capital stock in the Cananea Development Co., an operating company, have been turned over to the Cananea Central Copper Co. It is understood that the Cananea Central Copper Co. will itself be dissolved in the near future so that operations may be still further concentrated. This would leave the Greene Con. Copper Co. the only large subsidiary of the Greene-Cananea Copper Co. The Greene Consolidated dividend of 60c. per share was paid January 23 to the Greene-Cananea Copper Co., the owner of all but a small minority. Checks for \$30,000 were mailed to the minority stockholders.

The UTAH COPPER CO., in the quarter ended December 31, made a net profit from its milling operations of \$1,475,680. This combined with other revenue, from rents, Nevada Consolidated dividends, Bingham & Garfield railroad dividends, and miscellaneous sources, brought the total net profit of Utah Copper to \$2,157,765 for the period named. The income from Bingham & Garfield dividends does not represent the earnings of the railroad company merely during the quarter, but includes trackage rentals for the year. The dividends paid during the quarter amounted to \$1,177,012, leaving a net surplus of \$980,753. The earnings given are computed on a basis of 13.642c. per lb. for copper. At the end of the quarter no copper due for delivery from the refinery remained unsold. The entire Magna plant was operated throughout the quarter, but weather conditions reduced its capacity during November and December much below the normal of 12,000 tons per day. Six units of the Arthur plant have been in operation since the latter part of October, when the sixth remodeled plant was placed in commission. The seventh unit was put in operation about the middle of January, and from

present indications the capacity of the Arthur plant when all 13 units have been remodeled will be at least 8000 tons per day. There was 1,520,058 cu. yd. of capping removed from the Utah and Boston groups during the quarter, against 1,595,095 cu. yd. in the previous quarter, the reduction being caused by weather conditions. The Bingham & Garfield railroad during the quarter hauled an average of 7275 tons of ore per day from the mines to the mills. To provide for an increase in business this year, additional equipment has been ordered. The total amount of copper contained in concentrate for this quarter and the preceding three quarters of 1911, together with a comparison of the production for the year 1911 with the year 1910, is given below:

	Pounds.		Pounds.
January	6,797,116	April	8,169,248
February	7,329,326	May	8,391,879

Average monthly production for the year 1911.....	8,203,019		

The NEVADA CON. COPPER CO.'s income for the quarter ended December 31 was \$1,088,644. The payment of the ninth quarterly dividend, requiring \$749,389, left a net surplus of \$339,255. Depreciation on the Steptoe plant was placed at \$136,991, leaving a net credit to undivided profits of \$202,264. The December production was 4,679,674 lb. of copper, a smaller amount than for any other of the 15 months to be included in the coming annual report, owing to the unusually severe winter weather. While the settlement of the Veteran miners' strike permitted the resumption of operation on that property, production there was low, as there was much repair work to be done. The company during the quarter produced 15,434,788 lb. of copper. The production for the 15 months to be included in the annual report, which averaged 5,236,084 lb. per month, was as follows:

	Pounds.		Pounds.
October	4,980,306	January	5,268,954
November	5,207,353	February	4,992,533
December	5,510,936	March	5,632,256

Total	15,434,788		

Copper Producers' Association Figures

Production of copper for January was 119,337,753 lb., a decrease of 3,558,944 lb.; domestic deliveries, 62,343,991 lb., a decrease of 3,645,573 lb.; foreign deliveries, 90,167,904 lb., an increase of 929,188 lb.; total deliveries, 142,511,005 lb., a decrease of 2,715,385 pounds.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

C. F. MOORE was in San Francisco.

F. McRAE, of Reno, is in San Francisco.

CHARLES BUTTERS is in Central America.

GELASIO CAETANI is at Telluride, Colorado.

CHARLES W. GOODALE has gone to Winnipeg.

GEORGE W. STARR was in San Francisco this week.

WHITMAN SYMMES was in San Francisco Monday.

C. R. DOWNS, of Sutter Creek, was in San Francisco.

W. H. STORMS has returned from a trip to Ione and Placerville.

C. E. JULIHN has been appointed superintendent for the Union Con. and Sierra Nevada companies on the Comstock.

J. F. NEWSOM, F. L. SIZER, and G. H. CLEVINGER came up from Palo Alto to attend the Mining and Metallurgical Society meeting last Monday.

CHARLES J. COLL has resigned the position of general manager for the Acadia Coal Co., Ltd., Stellarton, Nova Scotia. Many regrets are being expressed at his departure from the province, since Mr. Coll was not only active in improving the technical and administrative management of the company, but also in public affairs, he having served as president of the Mining Society of Nova Scotia and as a member of the Council of the Canadian Mining Institute.

Obituary

JOHN HERRON, a well known mining engineer, died Saturday, February 3, as the result of an accident in the Pandora mine, at Telluride, Colorado, of which property he was in charge at the time of his death. Mr. Herron was 54 years old, having been born in India, December 31, 1857. He was educated at the University of Chicago, graduating with the class of 1880. He immediately took up railroad engineering, being first employed by J. F. Wallace on construction work in Illinois, and later, while still only 25 years old, he became chief engineer of a new road in Ohio. For many years he followed railroad engineering and bridge construction in the Middle West, but reached Montana in the early days of the construction of the Great Northern, where he was known as one of the most competent locating engineers. In 1893, owing to the total suspension of railroad construction in the Northwest, he accepted a position with the Montana Mining Co. at Maryville, Montana, as a draftsman, and remained with that company for five years, working up to the position of superintendent, in direct charge of all its mine operations. In 1898 Mr. Herron went to the Tomboy mine as general manager, and the English company operating that property, even after he was forced, as a result of a nervous break-down, to give up active charge of the mine in 1904, consulted him frequently. From 1906 until last July he has been engaged in consulting work and made numerous trips to Mexico for the purpose of examinations. John Herron's sterling qualities as well as his marked ability as an operating man, were known to those who were closely associated with him, but he was of a most retiring disposition, and could hardly be induced to speak of his own work. His absolute honesty would not permit him to claim quite all the credit even which really belonged to him. The news of his death will come as a shock to his many friends, and it is greatly to be regretted that the profession has lost one whose standards were so high and his personal character so admirable. He was a member of the American Society of Civil Engineers, the Montana Society of Engineers, and the Institution of Mining and Metallurgy. Mr. Herron's home has been at Palo Alto, California, for the past eight years, and he leaves a widow and a son and two daughters.

The Lewis Report on Copper

***Prices.**—Commencing with standard copper at £56 1s. 3d. per ton for cash, the closing quotation of the year was £63. The lowest points reached were £53 15s. 0d. on January 30 and £53 7s. 6d. on May 16, the highest being £64 2s. 6d. on December 21, when £65 was paid for three months prompt. During the first ten months the changes in prices were moderate—between £53 7s. 6d. and £57 10s. 0d. per ton—but, with the realization of the increasing strength of the statistical position, the market developed great activity during November and December, resulting in an advance from £55 cash to £65 for three months prompt, from which there was a reaction to £63 for cash, the sales of standard during these two months amounting to about 95,000 tons.

Standard copper fell £1 1s. 3d. per ton during the month of January—from £56 16s. 3d. to £53 15s. 0d. for cash, influenced by unfavorable American producers' returns and unsatisfactory advices with regard to American consumption, electrolytic copper being pressed for sale down to 12½c. per pound. Advantage was taken of the fall by dealers and speculators to buy freely, a good business being also done in manufactured copper with large purchases of Chile bars for conversion into sulphate of copper. In February the extreme prices were £55 11s. 3d. and £54 2s. 6d., the lower price being due to an increase of 9111 tons in the United States stocks during the previous month. Electrolytic sold at 12¾ to 12½c. per lb. for home consumption, and £57 5s. 0d. to £57 10s. 0d. per ton c.i.f. for export, chiefly to Germany. The demand was very dull and listless during March, cash standard fluctuating between £54 3s. 9d. and £55 2s. 6d., American stocks showing an increase of 6338 tons and European a decrease of 3445 tons. Standard fell to £53 11s. 3d. on April 19, but recovered again to £54 13s. 9d. Very large sales of American electrolytic and Lake copper were reported, both for home consumption and export, at 11½ to 12c. per lb., and £56 10s. 0d. per ton c.i.f. for the former and at 12½c. for the latter, the electrical and engineering industries both in England and on the Continent being very busy and a considerable quantity of manufactured copper being taken for India.

Pending the decision of the United States Supreme Court in the Standard Oil case, the demand in May was very inactive; but this, proving more satisfactory than was generally expected, exercised a favorable influence on the New York Stock Exchange and on American business generally, including the copper market, and resulted in an advance in standard from £53 7s. 6d. on May 16 to £55 7s. 6d. on May 24, with sales of about 24,000 tons—and in electrolytic from £55 15s. 0d. to £56 15s. 0d., the low level of prices and steady reduction of the European stocks, together with the prospect of increased American consumption, inducing large purchases by speculators as well as by consumers. The same influences further developed during June, and standard rose to £57 10s. 0d., the sales amounting to 24,000 tons, and electrolytic to £58 10s. 0d. per ton c.i.f., and 12¾c. per lb., large quantities of the latter being bought for export to Europe. In July, influenced by the political situation, the demand fell off and the fluctuations in standard were limited to a range of £1 5s. 0d. per ton—from £56 0s. 0d. to £57 5s. 0d., and in August to 16s. 3d. per ton—from £56 to £56 16s. 3d.—the serious labor troubles and excessive heat in Europe interfering with consumption, the effect of the favorable American statistics for the previous month being counteracted by the severe fall in American securities. The great depreciation in the value of securities on the New York, London, Paris, and Berlin stock exchanges; the advance in the rates of the Banks of England, France, Germany, and other European countries; the long drawn-out negotiations with regard to Morocco; the declaration of war between Italy and Turkey

and the occupation of Tripoli by the former power; exercised an adverse influence and caused much anxiety during September, resulting, however, in but a slight depreciation in the value of copper, standard falling from £56 3s. 9d. to £54 5s. 0d., but recovering to £55, while American electrolytic sold down to £57 5s. 0d. per ton c.i.f., and 12c. per lb. In October an exceptionally large business was recorded in English manufactured copper, induced by the reduced price at which American electrolytic was obtainable—down to £56 10s. 0d. per ton c.i.f.—and a fall in standard to £54 6s. 3d., of which large purchases were made for delivery in three months against sales of manufactured and sulphate of copper, the demand being stimulated by a large reduction in the English and French stocks, partly due to considerable exports of standard to Italy. Prices consequently recovered to £56 2s. 6d. for standard and £58 for electrolytic, the former subsequently falling to £55 5s. 0d.

In November a complete change came over the market, the attention of speculators, as well as consumers, being drawn to the increasing strength of the statistical position and the improved prospects of the metal, due to a reduction of 5154 tons in the European and of 2634 tons in the American stocks at the end of October, with a total increase of 34,932 tons in the European consumption and export, and of 3017 tons in the American consumption, as compared with the previous month, and the prospect of further increase. Large sales of electrolytic were made at 13c., and standard rose from £55 to £59 5s. 0d., with sales of about 45,000 tons. This advance made further progress during December, there being a further decrease of 6279 tons in European and of 10,362 tons in American stocks for November, and in the former of 3924 tons for December; standard improving to £64 2s. 6d. for cash and £65 for three months prompt on December 21, the total sales being about 50,000 tons, and electrolytic to £66 per ton c.i.f. and 14½c. per lb., large purchases being made by American manufacturers for delivery over three months as well as for export to Europe. The closing value of cash standard was £63.

Production in the United States has increased 15,020 tons or nearly 31½%, Lake Superior having decreased 1843 tons and Montana 5716 tons, while Arizona shows an increase of 7734 tons, and other states (chiefly Utah, Nevada, and New Mexico) 14,845 tons, the output of the 'porphyry' mines not having proved as large as was expected. Imports from 'other countries' into the United States have increased 7768 tons and into Germany 1720 tons, but into England and France they have decreased 1203 tons, German production increasing 640 tons. The total supplies have been 875,144 tons, against 851,199 tons in 1910—an increase of 23,945 tons, or 2½%. Increased production has not been very noticeable in any 'other country' except Queensland, which has sent 6500 tons to England, and Mexico—whence the increased supply to England and France has been 2650 tons. The shipments from Chile have fallen off about 6000 tons. At the Kansanshi mine in Rhodesia 1800 tons of fine copper has been produced and shipped to Europe, but smelting operations there have since been suspended pending arrangements for more economical transport from the mine to the railway. The prospect of large supplies from the Star of the Congo mine appears at present somewhat remote. Production of the world for 1911 may be estimated at 875,000 tons, as against 851,000 tons in 1910, 847,000 tons in 1909, 755,000 tons in 1908, and 720,000 tons in 1907, showing an irregular but persistent increase.

Consumption.—The forecast given in the annual report for 1910—that consumption promised to fall off to a considerable extent in the United States, but that in England and Germany there was every likelihood of it being maintained, if not increased—has proved correct. Whereas the consumption of the United States has been 13,941 tons less than during 1910, that of England has increased 856 tons, of Germany 18,318 tons, and of France 15,351 tons, while the exports of manufactured copper and sulphate of copper from England have increased 10,608 tons and of man-

*From the annual report of James Lewis & Son, Liverpool.

manufactured from Germany 8001 tons. Consumption, in long tons of fine copper, may be summarized as below:

	1910.	1911.
Consumption of the United States....	339,372	325,431
Consumption of England	96,336	97,192
Manufactured copper exported....	40,932	42,260
Sulphate of copper exported.....	10,678	19,958
Consumption of France.....	65,486	80,837
Consumption of Germany.....	117,169	135,487
Manufactured copper exported....	90,400	98,500
Consumption of American copper in Italy, Austria, and Russia.....	32,432	35,565
	792,904	835,230

Stocks in the United States and Europe have been reduced to the extent of 43,082 tons—100,693 tons against 143,775 tons a year ago. This follows a reduction of 23,685 tons during the year 1910, making a total in the two years of 66,767 tons. This shows the extent to which consumption has exceeded production.

Production and Consumption During 1912.—There is every likelihood of a considerable expansion of production in the United States in the course of the present year, the higher prices now ruling acting as a stimulus to it, but no

large increase is apparent from other countries with the exception of Russia, where the price rules much higher than in the rest of Europe, being protected by a high import duty. In the United States consumption promises to be much larger than last year, with the increased activity developed in the iron and steel trades and the cheapness of money, and in Europe there is every prospect of a continued large consumption, the electrical and engineering trades being supplied with orders for many months ahead. At present the tonnage of steamers under construction in the United Kingdom is 1,519,653 tons, against 1,131,503 tons at the end of 1910. Shipbuilders are expected to be very busy throughout the year not only with mercantile but also with war ships.

1. Imports into England.
2. Exports from England.
3. British production.
4. English home consumption.
5. Imports of all kinds into France direct.
6. Exports of English copper to France.
7. French consumption of copper imported direct.

8. French consumption of English copper and of copper imported direct.

9. English consumption and French consumption of copper imported direct and from England.

10. English consumption, English exports, and French consumption of copper imported direct.

Exports from Chile to all countries in 1910 amounted to 35,700 long tons of fine copper, and in 1911 to 29,700.

PRODUCTION EXPORTS AND IMPORTS

Production, imports, and exports of the United States, in long tons of fine copper, may be summarized as below:

	1910.	1911.
Lake Superior	98,839	96,996
Arizona	133,754	141,488
Montana	127,787	122,071
Other states and territories.....	124,553	139,398
Total	484,933	499,953
Imported	153,766	161,534
Total	638,699	661,487
Exported	310,316	346,041
Available supply	328,383	315,446
Stock, December 31.....	*52,299	*42,314

Consumption 339,372 325,431
*Omitting copper in transit and in process of refining.

STATISTICS OF EUROPEAN IMPORTS AND CONSUMPTION

Statistics of the import of copper produce into Liverpool, Swansea, London, and outports, in tons of fine copper, are given below:

Imports into Great Britain—	1910.	1911.
Chile	24,695	20,688
United States	39,493	47,631
Spain and Portugal.....	11,429	12,331
Ditto (precipitate)	9,186	7,447
Ditto (pyrite)	15,016	14,138
Australia	24,251	26,363
Cape and Namaqua.....	8,108	7,960
Japan	7,217	4,931
Norway and Sweden.....	1,267	1,140
Canada	1,482	2,304
Newfoundland	1,240	1,038
Mexico	10,614	12,073
Peru	3,649	4,051
River Plate	1
Africa	2,883	3,251
Venezuela	635	1,191
Other countries	1,015	1,341
Total	162,181	167,878

Imports into France—	1910.	1911.
Chile	2,483	2,735
United States	48,046	61,021
Mexico	6,125	7,316
Japan	1,775	2,926
Other countries	3,585	2,135
Total	62,014	76,136

Total imports into England and France	1910.	1911.
	224,195	244,014

Imports into Germany—	1910.	1911.
United States	159,346	169,829
England	5,150	2,275
Australia	8,380	4,432
Spain and Portugal.....	19,943	21,695
Other countries	18,703	22,619
Total	211,522	220,850

Production	1910.	1911.
	28,860	29,500

Total	1910.	1911.
	240,382	250,350
Exports—Unmanufactured copper ..	18,614	19,263
Manufactured copper	90,499	98,500

Total	1910.	1911.
	109,113	117,763
Stocks in Hamburg and Rotterdam, December 31	16,300	13,400
Consumption of Germany.....	117,169	135,487

Tin Production of Cornwall

The year 1911 was a satisfactory one for Cornwall, as far as the price of tin is concerned. The amount of tin concentrate sold at Redruth fortnightly ticketings has not been as great as in 1908 and 1909, but the total receipts have been substantially greater, as will be seen by reference to the following table.

	Tons of concentrate.	Total receipts. £	Average price. £ s. d.
1907	5,752 ¹ / ₂	597,599	104 13 0
1908	6,568 ¹ / ₂	508,756	77 9 0
1909	6,970 ¹ / ₂	539,245	77 7 2
1910	6,102 ¹ / ₂	549,096	89 19 7
1911	6,151 ¹ / ₄	702,599	114 4 5

Once more Dolcoath has been the largest producer, having sold 1699 tons for £197,896. The next in the list is Carn Brea & Tineroft, which produced 776 tons, selling for £82,787. As will be seen from the next table, no other mine came within 50% of these figures. As compared with the previous year, South Crofty showed an increase due to good management, and Levant and West Kitty showed a recovery.

	Total for 1911.		Total for 1910.	
	Tons.	Value.	Tons.	Value.
Dolcoath	1,699	£197,896	1,718	£160,328
Carn Brea & Tineroft	776 ¹ / ₂	82,787	930	73,756
South Crofty	678	76,275	632	56,652
Grenville	594 ¹ / ₂	70,308	614 ¹ / ₂	56,776
Basset	553	68,075	653	61,821
East Pool & Agar... ..	476 ¹ / ₂	53,587	507 ¹ / ₂	45,581
Levant	364 ¹ / ₂	41,982	189 ¹ / ₂	17,269
Wheal Kitty	173	20,101	230	22,307
West Kitty	134 ¹ / ₂	15,848	68	5,901
Geevor	115	12,504	97	8,357
St. Ives Consolidated ..	93	9,570
Wheal Hampton	78	8,057
Botallack	72 ³ / ₄	8,050	10	866
Tchidy Tin Streams.	34 ¹ / ₂	2,847	36	2,227
Phoenix	12	1,299	22 ¹ / ₂	1,902
Condurow	4 ¹ / ₂	455
Falmouth Con.....	81	7,204
Providence	24 ¹ / ₂	2,203
Parbola	7 ¹ / ₂	634
Wheal Vor	8 ¹ / ₂	678
Various small mines.	292	32,958	273	24,624
	6,151 ¹ / ₄	£702,599	6,102 ¹ / ₂	£549,096

It will be seen that Falmouth Consolidated, one of the Schiff-Dietzsch group, is not selling any concentrate at the ticketings nowadays. Presumably the output, if any, is sold by private contract in Cornwall or to Germany, probably to the latter, as better prices can be obtained there, and the directors have no connection with the Cornish community.

Hollinger Gold Mines

The Hollinger Gold Mines Co. will be merged with the Miller, Middleton, and Dixon Gillies groups in Porcupine, giving the new company 15 claims. Terms are now being worked out. The annual report of the Hollinger announces 462,000 tons of ore in sight, having gross value of \$10,230,000. Orebodies discovered every 100 ft. in depth should, it is estimated, yield approximately 225,000 tons with gross value of \$4,000,000 and net profits of \$2,500,000. Net profits for the next four to five years are placed at \$7,500,000. A mill which will cost \$275,000 will be ready for crushing 300 tons of ore per day in April. The cyanide plant will have a daily capacity of 500 tons. The company has accounts payable of \$150,401. The No. 1 vein has shown the greatest tonnage, 210,000, with a gross value of \$7,560,000. Below the 300-ft. level this vein every 100 ft. is expected to yield net profits of \$2,100,000. Development to date has amounted to 3717 feet.

Book Reviews

Any of the books noticed in these columns are for sale by or can be procured from, the MINING AND SCIENTIFIC PRESS.

ELECTRO-ANALYSIS. By Edgar F. Smith. Fifth edition, revised and enlarged. Pp. 332. Ill. P. Blakiston & Sons, Philadelphia, 1911. For sale by the *Mining and Scientific Press*. Price \$2.50.

This well known manual of electrolytic methods of analysis appears in revised form to include the methods in which improvement has been made in the past four years.

USEFUL RUSSIAN WEIGHTS AND MEASURES, WITH THEIR ENGLISH EQUIVALENTS. By W. A. Mercer. Pp. 4. London, 1911. Price 50c. For sale by the *Mining and Scientific Press*.

This is a convenient little table of Russian weights and measures, with their English equivalents. The addition of American equivalents would have added greatly to its serviceableness; grains per cubic yard and pennyweights per ton convey but little clearer ideas than dolis per 100 poods in the United States.

COMMERCIAL HANDBOOK OF CANADA (HEATON'S ANNUAL). By Ernest Heaton and J. B. Robinson. Pp. 397. Heaton's Agency, Toronto, 1912. Price \$1.25. For sale by the *Mining and Scientific Press*.

This is the standard authority upon the customs tariff, law and regulations of Canada, and also contains general information regarding Canada, and descriptions of towns, agricultural, and fruit districts, mining, railways, water-power, etc. It will be of much service to anyone contemplating travel or residence in Canada, and to professional men the chapter giving the requirements for the practice of a profession in each of the provinces will be useful.

A MANUAL OF FIRE ASSAYING. By Charles H. Fulton. Second edition, rewritten and enlarged. Pp. 205; ill. McGraw-Hill Book Co., New York, 1911. Price \$2. For sale by the *Mining and Scientific Press*.

The author has taken advantage of the issuing of a second edition to rewrite the text. No marked changes have been made, though several of the chapters have been added to. Mr. Fulton is well known for his writings on assaying and metallurgy, and it goes almost without saying that his presentation of the subject is at once lucid, accurate, and scholarly. Its excellence as a text-book is well known.
T. T. R.

METALLURGY OF IRON AND STEEL. By Bradley Stoughton. Second edition, revised. Pp. 537; ill. McGraw-Hill Book Co., New York, 1911. Price \$3. For sale by the *Mining and Scientific Press*.

The first edition of this admirable text was issued early in 1908, but the steady progress in the industry has made a thorough revision advisable. Thus the sections relating to the use of dry blast, electric smelting and refining, special open-hearth processes, case-hardening, and others, have been entirely rewritten, while minor changes have been made throughout, many of which add greatly to the convenience of use. New illustrations have been introduced, and an entirely new chapter, on metallurgical fuels, has been added. Both for classroom use and for the general reader, this is unquestionably the best brief treatment of the metallurgy of iron and steel now available. T. T. R.

The statistical bureau of the convention of the owners of oilfields in Baku (Caucasus) reckons that the total shortage of oil in Russia from all the oilfields for 1911 amounts to 630,000 tons. The output on Teheleken island and at Grozni equals that of 1910, while an increase of 90,000 tons is reported for Maikop, which has little effect on the enormous Baku deficit. The opinion is expressed that a serious lack of oil may soon be expected. Dealers in oil who have bound themselves by contracts will be obliged to pay high prices.

Commercial Paragraphs

JAMES IRVING & Co., of Los Angeles, Cal., refiners and assayers, have moved to 107 North Spring street.

C. A. DELANEY has been appointed Western representative of the AMERICAN LOCOMOTIVE Co., with offices in the McCormick building, Chicago.

The WAGNER ELECTRIC MFG. Co. of St. Louis announces the removal of its San Francisco office to the Rialto building. A. J. Myers continues in charge.

The rapidly increasing demand in Pittsburg and vicinity for the asbestos, magnesite, and other products of the H. W. JOHNS-MANVILLE Co., has necessitated a move from its present location in Liberty avenue, above Ninth street, to larger quarters. After January 24, 1912, the Pittsburg branch of the H. W. JOHNS-MANVILLE Co. will therefore occupy the entire eight-story stone, reinforced concrete, and steel building at the northeast corner of Wood street and First avenue.

Catalogues Received

THE HAYWARD Co., 50 Church St., New York. Pamphlet No. 579. Illustrating various excavating machinery manufactured by this company. 7¼ by 9 inches.

SMITH-BOOTH-USHER Co., Los Angeles, Cal. Catalogue 'A,' covering its line of machinery, supplies, pipe, and fittings for mines, mills, irrigation and power plants, etc. 8 by 7 in. 576 pages. Illustrated.

UNION IRON WORKS Co., San Francisco. Catalogue No. 5. 'Evans Hydraulic Elevators and Hydraulic Mining Machinery.' 24 pages. Illustrated. 6¾ by 10¼ inches. Contains also valuable table for hydraulic and mining engineers.

INGERSOLL-RAND Co., 11 Broadway, New York. Bulletin No. 4016. 'MC-22.' 'Telescope Feed Hammer Drill.' 12 pages. Illustrated. 6 by 9 inches. Also Bulletin No. 4204. 'Arc Valve Tappet Rock Drills.' 16 pages. Illustrated. 6 by 9 inches.

DURING 1910 there was a falling off in the production of Indian diamonds, which are found mainly in central India. The total quantity obtained in 1910 was only 77.74 carats, valued at \$2950, as against 147,355, valued at \$5445 in 1909. It is apparent that diamond mining in India at the present time amounts to very little, and it is predicted that as a business it will cease altogether within a short time unless some large company undertakes the development of the mines in central India. This will require a tremendous outlay for building roads to make the mines accessible. There is no doubt that very rich diamond fields exist in India, but in such out of the way places and so difficult and dangerous of access that they are not workable by individuals of small means.

THE minerals that were mined in Great Britain during 1910 amounted to \$594,226,815, an increase over 1909 of \$13,278,941. This increase was due principally to the advance in the value of coal. The output of iron ore was 15,226,015 tons, valued at \$19,574,372. This ore yielded 4,975,735 tons of iron, which amounted to nearly one-half of the whole quantity of pig iron made in the United Kingdom.

THE production of petroleum in the south of Asia is confined principally to Burma and amounted to 214,829,647 gal. in 1910, compared with 233,678,087 in 1909. The imports of kerosene into India declined from 70,514,379 gal. in 1909 to 57,359,905 gal. in 1910.

THE Bunker Hill & Sullivan Mining & Concentrating Co., on February 5, paid dividend No. 173, of \$65,400. This makes the total amount of dividends paid \$13,290,450.

THE gold production of India during 1910 amounted to 573,119 oz., as compared with 574,816 oz. in 1909, the value each year being about \$11,000,000.

EDITORIAL

BRAZIL is buying American steel rails, the United States Steel Products Company having taken an order for 25,000 tons for shipment to that country.

SILVER continues to advance, having been quoted at 60⁵/₈ cents at New York and 27⁷/₈ pence in London on Tuesday, the highest price in some years. The rise is generally ascribed to the expected demands of the new Chinese republic, as well as heavy purchases in London for India.

NOME is reported to be facing a fuel famine. According to figures that we published January 6, the winter population this year is 2118, and the stock of coal at the close of navigation was 7660 tons. This has been supplemented by fuel oil and coal furnished by dredging companies, but it is still probable that an ice-breaking steamer will have to be sent in before spring.

STAMP-MILLING problems have always been the source of study by South African engineers, and we reproduce this week an article by Mr. H. Stadler which will be at once a source of interest and of useful information. If present-day problems were similarly made objects of concerted study by technical societies in America, their transactions would profit greatly in usefulness and interest.

NICARAGUA has long been a source of much attraction to engineers, and with the approaching completion of the Panama canal, seems likely to enjoy greater prosperity, together with her sister Central American republics. Elsewhere in this issue Mr. Oscar H. Hershey writes of the geology of the Pis Pis district, near the northeast coast, and later we hope to present a detailed description of the mines near the western coast, which are less well known.

BUTTE is making notable progress, and the mining companies there are increasing their output. The February production of the Anaconda is expected to reach 26,000,000 pounds. The more extensive use of electricity and compressed air and other mechanical improvements is contributing to reduce the cost of production, while the grade of the ore in depth is remarkably good. The problem of saving finely crushed sulphides is being attacked by centrifugal concentration, and the district's future bids fair to vie with its notable past.

TECHNICAL education rightly should rest upon the surest foundations, and the trustees of Columbia University are to be congratulated on the recognition of the increasing need in America of engineers whose professional knowledge rests upon the broadest possible general foundations, shown in the adoption of a plan providing for a three years' course in the various branches of engineering which must be preceded by three years' study in a college or scientific school of high rank. It is interesting also to note that the alumni committee on technical education, having considered the matter from a business standpoint, reported that as the cost of education at Columbia is neces-

sarily very high, the return to the student should be of correspondingly high quality.

ANNOUNCEMENT of the annual meeting of the American Institute of Mining Engineers was given in our columns last week. Every member who can should attend the meeting, or, failing that, should forward his proxy before it is too late. In our 'Discussion' columns we last week printed a letter sent out by a notable group of members who announce as their aim the decentralization and broadening of the scope of the Institute in order to make it more useful to the widely scattered membership. It may be worth while to remind members that it is not necessary to give proxies only to some one of those who have already requested them; any friend who attends the meeting and is in sympathy with your views can vote for you if you provide him with a proxy in due form. We hope that the great general interest taken in this business meeting may be a precursor of a livelier interest and participation of the membership in the technical activities of the Institute.

IN the death of George Jarvis Brush, former director of the Sheffield Scientific School of Yale, a notable figure passes from the field of action. A graduate of Yale in the class of 1852, of which he was the last surviving member, he studied abroad, at Munich, the Royal Saxony School of Mines, and the Royal School of Mines in London. Returning to America he joined the faculty of his alma mater, with which he was connected until his retirement from active service in 1899. He was a member of many learned societies, to which he lent distinction as well as service, and Harvard conferred the degree of LL.D. upon him in 1886. For many years professor of metallurgy as well as of mineralogy, he held at Yale much the same position and influence as Thomas Egleston at Columbia, and both men left an indelible impress upon the development of metallurgy as well as mineralogy. Members of the profession everywhere will join with Yale men in mourning his going before.

DISCUSSION of anti-trust legislation from many points of view is needed. We print this week the argument made before the Senate Committee at Washington in behalf of the coal operators, by Mr. G. W. Traer. It is an especially significant document, not only because it has the approval of several of the great associations of coal operators, but because it was prepared by an able and conscientious leader among business men. Mr. Traer was originally trained for the bar, but turned instead to business, first in railway development, and then in coal mining. As representative of the J. C. Osgood interests, and later of others, he has had an active business career which, however, has not prevented his maintaining the mental attitude of a student. He is widely known as former chairman of interstate joint conventions of the operators and miners. What he says is based upon detailed knowledge of actual conditions in one of the great mining industries of the country.

ESTABLISHMENT of a republic in China by imperial decree was the news feature of the past week, and, to those familiar with the social conditions in that country, it is not surprising that the change has been unmarked by popular demonstration. In no other country in the world does the average citizen come into so little touch with the central governing authority, and the change of government will have little immediate effect upon the masses. The crucial problem of the new republic will be finance, one that has already too long been met with makeshifts. Fortunately a strong man is now at the head of affairs in Peking and we hope that the outcome will be a united, progressive,

and prosperous China, ready to do business with the rest of the world in a businesslike way. The exports from the United States to China have grown from a value of eleven million dollars in 1900 to twenty-three million dollars in 1911, while our imports last year amounted to thirty-two million dollars worth of goods. Continued growth of trade and increasing trade relations will benefit both republics.

RAND shareholders will in future be allowed to see yearly reports before sending in their proxies, so that opportunity may be afforded for learning what action is proposed and what necessary. The right of the shareholders to information as to proposed courses of action of the directorate is too frequently ignored, but those who oppose such a course of action are often but little more lucid in their statements. An instance of this is seen in the recent purchase of shares in the North Dome by the management of the Temiskaming Mining Company, where an association which has been formed to oust the management is sending out requests to shareholders for proxies for that purpose. Some shareholders have, properly enough, replied that while they were not informed of the previous actions of the management, neither are they properly enlightened as to what is now proposed to be done, and are not disposed to sign away their rights without a definite understanding of the exact use to which the proxy will be put. The exigencies of the moment at times preclude consulting the wishes of shareholders, and the necessities of business diplomacy sometimes prevent open discussion, but the shareholder is, nevertheless, a partner in the enterprise and should receive the fullest information possible to convey. Frankness will pay in the end.

NATIONS of the Old World are buying copper, and the low-hanging war cloud, which seems to be endeavoring to envelop all of Europe in its folds, is now openly discussed as the reason for the phenomenal export demand which in turn is responsible for the figures of the Producers' Association for January. European nerves are evidently all a-jangle, and each incident in public affairs receives a sinister interpretation. Behind all the discussion of peace committees and arbitration courts lies a market conviction that war will prove inevitable, and there can be no questioning, in seriousness, the source of the demand which has cut the accumulated stocks in this country to a low mark of 66,280,643 pounds. The decrease in surplus for the month was 23,174,052 pounds. Of the month's production of 119,337,753 pounds, foreign demand accounted for 80,167,904 pounds, totaling a larger foreign shipment than for any one month of 1911, and exceeded only by January and December in 1910. Were conditions settled in other lines, the business atmosphere a normal one, it would be safe to predict a sharp rise in copper and an immediate access of activity in copper shares. As matters stand, the armies of Europe are apparently under orders to sleep upon their arms; on our own side of the water, there is much discussion of the possibility of reluctant intervention in Mexico. It follows, therefore, that a copper boom, if launched now, must be founded upon the world's unrest, rather than upon the normal growth of commercial enterprise, and the very factors which create the demand will so far unsettle business conditions as to largely diminish the profits derived.

The Improbability of Impartiality

In the mechanical world, whenever a new piece of apparatus has been successfully constructed, one of the first duties of the manufacturer is to standardize its parts in order to conduce to convenience in its use and repair. In

the realm of ideas a thoughtful observer can scarcely fail to detect a similar tendency toward standardization of ideas and methods of thought, presumably to make thinking less difficult. Essays and articles may be found in which standardized ideas, like building stones, are put together with but the scantiest bond of the cement of originality to form a more or less useful and harmonious whole. This is not only convenient but is oftentimes necessary, for in the complexity of modern life every energetic man finds more demands upon his activities than he can well meet, and is commonly forced to do things in the easiest and most effective way rather than in the ideal way. But such standardized ideas must be cleanly cut, like ashlar masonry, and this introduces the difficulty that they can thus only with difficulty be adjusted to the border line of fact, which is seldom definite and clear.

An example of this is seen in the common assumption that certain persons are, by virtue of their training and surroundings, impartial while others are similarly partial, an assumption voiced by a friend who remarked that complete reliance could not be placed upon articles appearing in technical journals, because they were in many cases prepared by men who were interested in the object of discussion and therefore could not treat it impartially. The superficiality of this reasoning must be evident, for it involves the fallacious belief that one who has no interest in an object will therefore be impartial in his discussion of it, while one interested will necessarily be partial. It is rare indeed that anyone is perfectly and consistently impartial, for even the mathematicians, who might, of all classes of men, be expected to attain freedom from mental bias, seem but little freer from disputes than other classes of men. In the solution of scientific problems investigators cling to the methods which appeal to them, and in their comparisons of various types of machinery or methods of work college professors inevitably emphasize those which they have had most opportunity to study in detail, awarding a less proportion of attention than is their due to those with which they are less familiar. On the other hand, the description of his own device by an inventor is sometimes modest in the extreme and entirely free from the tendency toward exaggeration observable in the writings of one who is endeavoring to prove a point or establish a principle.

The real criterion is found in the analytical perusal of what the author has to offer his readers. There is no *a priori* reason why a description by John Smith of the Smith process or machine should be untrustworthy; and whether it is or not will depend upon the ability and intellectual honesty of Mr. Smith. If his intelligence is limited he may attempt to claim impossible virtues and efficiencies, much as vendors of patent medicines once did. The inadvisability of such a course of action is generally recognized, as is evidenced by the infrequency of its use, and the description of an object by one interested in it is commonly reasonably fair and impartial, at times even more impartial than a similar description by a more enthusiastic observer who has no direct interest in the matter. The difficulty lies, perhaps, in confusing material interest and impersonal interest, for it not infrequently happens that enthusiastic observers will make larger claims for a machine or a process than will its inventor. Authors of technical articles cannot therefore be arbitrarily divided into those who are partial and those who are not, for no such clear line of distinction exists and the reader must intelligently consider what he reads.

Mental bias in an author may be perfectly unconscious and is often a matter of temperament; one man naturally inclines toward commending the good features, his neighbor as naturally looks for flaws and difficulties; one man gives

a process or machine the benefit of the doubt, another concedes no more than is demonstrated. An accurate picture can not be obtained from the account of a single observer, as in the well worn story of the blind men and the elephant. By recognizing that no man is truly impartial, even though he consciously strive to attain it, and that a description by an interested person is not necessarily more partial than one by an outsider, a clearer perception of the value of technical descriptions may be gained.

Government Bureaus

Last week we published the text of a proposed bill amending the act creating the Bureau of Mines, and in our Washington letter this week some further details are given. A curious feature of much of the comment made upon the changes in the act is an apparent fear that the Bureau will do too much, and that it is therefore necessary to carefully restrict its activities. This can scarcely be based upon a desire to prevent the expenditure of public funds upon unnecessary work, for proposals to establish metallurgical experiment stations at various points throughout the West have been able to elicit no little public support. One of the stock arguments against the increase of Government activities beyond the necessary fields of legal administration is that the Government is unable to conduct any enterprise as cheaply as private corporations. The fact is ignored that where this is true it commonly arises from restrictions which hamper the methods of Government work, making them unduly expensive, and at times serving to prevent prompt and necessary action. A good example of this last is just at present seen in California, where the safety of some of the oilfields is being threatened by water. Concerted action by the operators to meet the situation is difficult to secure, and the State Mineralogist, who might properly take the lead in such a matter, is unprovided with funds for any such work, nor will the law permit him to make use of funds which the operators are willing to furnish. Thus a bureau created to advance the interests of the mineral industry is unable to act effectively because those who considered it necessary to properly circumscribe its scope were unable to foresee any such contingency. Flexibility and effectiveness is what is really desired, and in business circles this is secured by outlining the general scope of the work, securing a capable and trustworthy head, and leaving special problems to him to be settled as they arise. There is no good reason why a Government bureau should be organized on any other than a business basis.

Some criticism of proposed changes is apparently based on ignorance of what is already being done. For some time the Bureau has been making tests upon explosives, and early last year fees were imposed for doing this work, in order that manufacturers might not avail themselves of the privilege except when necessary. It is quite on the cards that it may be found desirable in the future for the Bureau to make other tests, such as are now being made in other lines of work by the Bureau of Standards, and provision should be made for this. Work of this sort is a proper phase of government activity, both because of the desirability of having it performed under auspices which prevent the possibility of bias, and because the total quantity of this work is small and the necessary equipment expensive, so that it could scarcely be made an object of commercial enterprise. Metallurgical testing stations are quite another affair, and our opinions upon them have already been adequately expressed. If any criticism may be lodged against the amended act by the metal miner it is that it errs on the side of conservatism rather than of too much freedom for the Bureau.

Plea for Revision of the Sherman Act

By G. W. TRAER

*On behalf of the Illinois Coal Operators' Association, I desire to offer the following suggestions for amendment of the so-called anti-trust laws, together with comments intended to disclose the reasoning upon which our suggestions are based. We believe that all improper trust methods or practices may be divided into three classes, that is to say:

1. Attempted monopoly; or attempts to effectuate by agreements or combinations of individuals, partnerships, or corporations, those results of monopoly for which it is condemned; namely, the fixing of arbitrary control of prices or the limiting of output below actual public needs.

2. Methods and practices by either individuals, partnerships, or corporations toward competitors, of such character as to require, in the public interest, prohibition and punishment under the law of criminal conspiracy.

3. Excessive issuance of securities by corporations, resulting in abnormal and improper absorption of capital for speculative purposes alone and not for the purpose of increasing efficiency.

REMEDIES ARE PROPOSED

We therefore suggest changes in the law as follows:

(1.) That the Sherman act be amended so as to eliminate prohibition of 'restraint of trade' and substitute therefor prohibition of agreements or combinations by either buyers or sellers, the purpose or necessary effect of which shall be to fix or arbitrarily control prices or limit output. The prohibition of monopoly or attempted monopoly to remain as at present.

(2.) That a trade commission, composed of a suitable number of members, be appointed by the President, under the terms of a statute separate and distinct from the Sherman act, providing for such commission and prescribing its powers.

(3.) That all persons, firms, and corporations be subject to the jurisdiction of the Federal trade commission, with respect to all agreements or combinations which regulate or tend to regulate interstate trade or commerce.

(4.) That the trade commission have power to investigate all contracts and combinations which tend to or do create a monopoly or regulate or restrain interstate trade or commerce; and to make findings determining whether the same are in violation of the Sherman act as amended.

(5.) Appeals to be provided from the decision of the commission to the present Commerce Court or another special court created for the express purpose.

(6.) A requirement that makers of such contracts or combinations shall submit the same to the commission for determination as to whether they create a monopoly or unlawful restraint of trade; and if they shall obey an order of dissolution by the commission or by final order of court upon appeal, they shall be subject to no penalty by reason of the contract or combination.

(7.) Provision that the commission may hear and investigate without complaint from third parties, and shall do so upon such complaint; but there shall be no penalty in such cases unless it shall be found that the defendants intended the purpose and necessary effect to be to fix or arbitrarily control prices or limit output or create a monopoly.

(8.) A national incorporation act does not appear to be essential to the effective regulation of attempted monopoly or contracts or combinations in restraint of trade. Monopoly might be effected by a single individual. Unreasonable and vicious restraint of trade might be effected by agreement or concerted action between two individuals.

It seems clear, however, that if the capitalization of

and issuance of securities by corporations engaged in interstate trade, is to be effectively regulated, it will have to be done by the Federal government. We believe it will prove advisable to permit the issuance of new securities as a basis which will permit of reasonable speculation on the future, as a reasonable stimulus to enterprise. Extreme conservatism in this respect would give too great advantage to those already in business at any given time, and would work serious public harm by restricting development. A well organized bureau of corporations would seem to be a better place for the handling of these matters than a trade commission also charged with the regulation of the acts of individuals and partnerships as well as corporations.

Agreements and combinations and concerted action designed to 'stifle', 'strangle', or 'throttle' competition by unlawful acts are now punishable under the law of criminal conspiracy and should remain so. But such conduct is not attributable to corporations alone. A bureau of corporations or any other agency for controlling corporations as such, would not seem as suitable a place for investigating and prosecuting such conduct as a trade commission. In the investigation of alleged attempts to monopolize or unreasonably restrain trade, a trade commission would almost certainly unearth criminal conspiracy if such existed; and in case of such discovery it should be the duty of the commission to present the evidence to the proper officers of the law. Summarized in reverse order, our suggestions are:

That the prevention of improper issuance of securities by corporations engaged in interstate trade may be effected best by a bureau of corporations, through the medium of a national incorporation act requiring a Federal charter for such corporations.

That a trade commission shall be created, one duty of which shall be to investigate agreements, combinations, or concerted action among two or more individuals, partnerships, or corporations, the purpose or necessary effect of which shall be to 'stifle', 'strangle' or 'throttle' competition and to cause the prosecution of the same under the law of criminal conspiracy. By this means unlawful acts of competitors toward each other may be prevented.

That in place of the indefinite expression "restraint of trade" in the anti-trust law, there be substituted the explicit expressions "fixing or arbitrarily controlling prices or limiting output by combinations either of sellers or buyers"; and that all agreements or combinations regulating or tending to regulate trade or production be subject to the jurisdiction of the trade commission as suggested above. By this means concerted acts of either sellers or buyers toward the other, which are publicly harmful, may be prevented.

CONDITION OF COAL INDUSTRY

If the committee please, I should like also to describe as briefly as possible, the conditions existing in the bituminous coal-mining industry of Illinois which relate to the subject-matter of the suggestions we have presented.

There are about 300 independent coal-producing companies in the state, operating more than 400 rail-shipping mines. The annual consumption of Illinois coal is about 50,000,000 tons. The annual capacity of the mines, if worked throughout the year to the full extent of actual transportation facilities, would be about 75,000,000 tons. Public necessity seems to require that there shall be in existence at all times sufficient mining capacity to supply the greater requirements of the winter months. This inevitably means a large surplus capacity during the spring and summer months. The natural fluctuation in the demand for Illinois coal between summer and winter is such that the industry never can expect to work full time.

*Address delivered Thursday, February 1, before the Committee on Interstate Trade and Commerce of the United States, at Washington, and published in *The Black Diamond*.

While Illinois coal can be stocked a considerable length of time, it cannot be mined many months in advance and held for use in the winter, like anthracite and more expensive Eastern bituminous coals, because it contains a higher percentage of moisture and will crumble and slack sooner than the higher-priced coals. Consumers of Illinois coals aggravate, rather than help to overcome this condition by refusing to order coal as much as might be, in advance of the actual need for it. It must be produced substantially as ordered from time to time, and this makes the production or demand (and demand and production mean the same thing in this connection), much less during the months of April to September, inclusive, than during the other months of the year. This condition is so uniform that the relative percentages of production during the busy season and the duller season have not varied materially in ten years, except when temporarily affected by anticipation of a strike or other abnormal business conditions.

After making all allowances for Sundays, holidays, and other usual stoppages, it is fair to say that the excessive producing capacity results in an average loss of 60 days per annum for all mines, compared with what might be properly expected with a reasonable adjustment of the number of mines attempting to run, to the number actually required to fully and promptly supply all demands.

There are more than 70,000 miners and mine laborers at the mines in Illinois, working on the average 60 days per year less than they could work if there were a reasonable adjustment of producing capacity. This is equivalent to the absolute idleness for the entire year of 12,000 to 15,000 men. The very low average number of days' operation causes coal to cost much more than it would if fewer mines were operated a greater number of days.

The intense economy forced upon the mine-owners by these conditions is seriously affecting the proper conservation of the coal deposits. The general population of the communities in which coal mines are situated as a rule are suffering greatly in their business affairs.

ADVANTAGE OF BUYERS

Under the conditions I have described the seller of coal practically is under duress as compared with the buyer. A seller in deciding whether to deal with any given buyer should have at least some reasonable equality of alternative advantage or disadvantage, but the producer of coal under these conditions has no equality of choice. If a coal mine stands idle, physical deterioration proceeds with great rapidity. In many cases large quantities of water must be pumped out constantly or the mine will be flooded and destroyed, while in others underground fires from spontaneous combustion must be guarded against constantly. A heavy additional penalty is thus imposed upon the mine-owner who might otherwise choose to let his mine remain idle instead of producing and selling coal at a direct loss. A merchant or manufacturer is not put to the choice of selling at a loss or being put to ruinous expense to avoid having his store or factory flooded or burned, nor is the deterioration of an idle building or machinery comparable in any degree with that of an idle mine.

The buyer is in an entirely different position than the seller. Presumably, any two buyers, or any number in fact, may legally combine to place their purchases with this or that seller at their pleasure. No doubt it is true that such a combination of buyers, by misrepresentation of facts or other acts of a fraudulent nature, might be held punishable for conspiracy to defraud. But in such case the legal offense would consist solely of the misrepresentation or the fraudulent acts. The mere combination to purchase jointly is not condemned either by common law or statute.

There are numerous things which could be done by combination or coöperation, in the way of regulating production and distribution, with a view to reducing the cost of producing and distributing the coal and maintaining the properties; and which, at the same time, would result in direct benefit to the miners and mine laborers and to mining communities generally. The general public would be

benefited also in so far as improved methods should result in better condition of the coal in the ground and lessened waste of capital and labor from overdevelopment, overproduction, and overcompetition. But it is practically impossible to effect by combination or coöperation any improvement in methods of production and distribution without at the same time lessening to some extent unreasonable or destructive competition; although such movements need not necessarily nor should they be permitted to go to the extent of fixing or arbitrarily controlling prices, limiting output, or eliminating fair and reasonable competition.

We do not believe the general good requires that combination or coöperation shall be illegal merely because it lessens the number of competitors in an industry, or because it reasonably regulates production and distribution, or because it may have some effect on prices.

Lessening the number of competitors may occur whenever two or more individuals engage in a partnership or form a corporation, or when several small corporations are merged in a large one. But this is not generally regarded as dangerous unless carried to the extent of practically arbitrary control of the situation.

Regulation of production and distribution or coöperation, even if it should have a material incidental effect on strained or destructive competition and thereby on prices which have been forced below the fair cost of production and distribution, has not yet been publicly condemned and should not necessarily be, unless it goes to the extent of giving practically arbitrary control to seller against buyer.

We believe that these principles should be recognized in framing and administering the laws, namely, that just as unreasonable combination leads to no competition, so no combination leads to unreasonable competition; and that competition without counter-check or reasonable regulation destroys itself and leads to consolidated ownership in units whose most conspicuous attribute frequently is tremendous and ominous financial power, rather than increased efficiency. The history of the coal-producing industry has exemplified these principles in the past and is continuing to do so today.

The Van Roi Mines

Four years ago the Le Roi No. 2 company issued a subsidiary called the Van Roi, for the purpose of acquiring the Vancouver group of silver-lead-zinc properties in the Slocan district of British Columbia. The capital is £34,500, divided into 30,000 preferred shares of £1 each and 90,000 common shares of 1s. each. The purchase price was £20,000 cash paid to the local owners, and 60,000 common shares paid to the Le Roi No. 2 company. At first, the company continued to send the ore to the Wakefield mill for concentration, but this arrangement ceased in August 1910. Subsequently a new mill was built on the other side of the mountain, and an adit driven to deliver the ore; also the aerial tramway was moved to the new position. Operation was resumed on March 15 of last year. The report, covering the year ended September 30, shows that during the 6½ months, 22,427 tons of ore was sent to the concentrator, averaging 3.74% lead, 7.86% zinc, and 9.46 oz. silver. The production was 1214 tons of lead concentrate, averaging 65.36% lead, 9.16% zinc, and 89.7 oz. silver, and 1598 tons of zinc concentrate averaging 45.5% zinc, 1.76% lead, and 29.6 oz. silver. The tailing assayed 0.16% lead, 4.65% zinc, and 3.26 oz. silver. The profit and loss account shows a debit of £2661. Since the end of the year under review, the company has been making a profit, and the directors and managers are hopeful of the future.

According to *The Engineer*, foreign patents are being applied for by Chr. Oftedahl, of Christiania, for a chemical process whereby he claims that iron and steel plates may be hardened and made unpierceable, while at the same time their normal elasticity is maintained. The inventor claims that the chemical substance required can be added during the actual process of rolling. Experiments are contemplated at the mills of a large foreign works.

Geology of the Pis Pis Mining District in Nicaragua

By OSCAR H. HERSHEY

The Pis Pis mining district in Nicaragua comprises an area about 11 miles long in a northeast direction, and about $1\frac{1}{4}$ miles wide. It is situated in the valley of the Pis Pis river (a tributary of the Waspue river), on the divide which separates that stream from the Tunkey and Banbana rivers (tributaries of the Prinzapulea river), and in the basin of the Tunkey river. Its exact situation is not known, but it has an estimated distance from Cape Gracias á Dios of about 225 miles by the Wanks, Waspue, and Pis Pis rivers, and from Prinzapulea of about 195 miles by the Prinzapulea, Banbana, and Tunkey rivers.

In the spring of 1910 I accompanied a party of mining engineers to the Pis Pis district and spent about 15 days in it. The general character of the rocks was evident in the field, but to get an expert petrographer's opinion on the names that should be applied to them, a set of thin sections was submitted to A. C. Lawson, of the University of California. They were studied by a student at the university, but his report was reviewed and amended by Mr. Lawson. The detailed descriptive notes have been incorporated in a paper entitled 'Geological Reconnaissance in Northeastern Nicaragua' which was read by title at the March 1911 meeting of the Cordilleran Section of the Geological Society of America and will be printed in the bulletin of that Society. It is not my purpose to go at length into the general geology, but to treat the subject rather from an economic standpoint.

The greater portion of the district is occupied by a thick series of andesite lavas and fragmental rocks, to much of which the term augite-andesite may be applied. Scattered through this are dikes and irregular masses of a harder andesite, to which also the term augite-andesite is applicable.

The northeastern portion of the district is characterized by a mass of intrusive rhyolite about 4 miles long and 1 mile in maximum width. Rhyolite also occurs in a narrow band of hard, flinty-appearing rock that has given rise to the Big falls on the Pis Pis river. A portion of the foot-wall of the Bonanza vein has an appearance suggesting a partly decomposed diorite, but no material fresh enough for microscopic study could be secured. The approximate distribution of these rocks will be given in a map that will accompany the paper mentioned above.

The Pis Pis district is traversed by a remarkable system of large gold-quartz veins. All the larger veins have a northeast-southwest course and dip northwest at angles varying from 45 to 75°. Some of the smaller veins are transverse to the large ones. All have resemblances which indicate that they are members of one system, but each has some character distinguishing it from the others. They were deposited in actual open fissures which were probably reopened from time to time, producing a fairly definite ribbon structure. The gangue is generally a fine-grained quartz, in part hard and barren, and in part impregnated by sulphides. Crustification is common, and there are many crystal-lined vugs. Generally there is no evidence of metasomatic replacement, but in places there are fragments of country rock in the vein which may in part have been replaced by quartz and sulphides. In the Bonanza and neighboring veins much of the unoxidized ore has a green stain, evidently due to chlorite.

The sulphides almost invariably present below the zone of oxidation are pyrite, galena, sphalerite, and chalcopyrite, in greatly varying proportions. The mines are in two groups, the northeastern and southwestern, with a space of about $3\frac{1}{3}$ miles between, in which the veins are present, but not denuded and developed. The northeastern mines (except the Lone Star and Panama) including the Bonanza, Mars, and Neptune are grouped about the rhyolite area. They are relatively rich in quartz and low in

sulphide content. The Lone Star is in intrusive augite-andesite at some distance from the rhyolite area, and it shows an increase of sulphide, particularly galena. The southwestern group, including the Siempre Viva, Constancia, Concordia, and Trinidad mines, is in andesite, and relatively rich in sulphides. The veins of this group are characterized by the presence of a large quantity of fine-grained hematite (specularite). Thus I have gained the impression that the veins cutting the basic rocks are richer in sulphides and other basic minerals than those in and near the rhyolite area, making it more difficult to extract the gold from the sulphide ore. The Bonanza and Mars veins are quite favorable in this respect.

The country rock bordering the large veins abounds in seams of quartz extending 30 to 100 ft. from the vein proper. They consist of the same kind of quartz and sulphides as the large veins, and doubtless carry gold, but it does not appear that they have made any important orebodies. These stringers are best developed in the extrusive andesite, least in the rhyolite.

Aside from these facts, I cannot see that the country rock has had any important influence over the veins. They are developed in all the formations of the district and pass readily from one to another. I could not secure any good evidence that the deposition of the gold has been controlled by the wall-rock. The large veins are in the form of a succession of lenses which may be 50 to 500 ft. long and 10 to 85 ft. in maximum width, connected by short stringers of quartz 6 in. to 3 ft. thick. It is a rule throughout the district that the wider portions of the veins are richer in gold than the narrower portions; but the smaller veins, called *hilos* (threads), 2 to 5 ft. thick, and which are often spurs from the large veins, are generally of higher-grade ore than the large veins. Mine-owners in the district try to connect the Siempre Viva, Lone Star, and Mars veins as one vein about 10 miles long, but I think the large veins are only 1 to 3 miles long, dying out into a group of stringers.

Although the veins are in strong fissures, there is not much evidence that they are due to faulting. Strong gouges are not often present along the walls, and the gouges present are as likely to be within the veins as on the walls, and are perhaps due to comparatively recent movements. The distribution of the wall-rocks along the veins in a few cases indicates some displacement, but I believe that in general faulting has not been an important feature. As to transverse post-mineral faulting, there has been little of it; only one important fault of this nature was detected.

I can see no reason why, at any depth at which these veins are cutting the same formations as appear at the surface, they should not be as strongly developed and carry the same content in gold and silver as they do in the upper part of the sulphide zone, except possibly such decrease in value with depth as may be common to gold-quartz veins in general. I can see no evidence of secondary enrichment below the zone of oxidation. When the veins pass beneath the volcanic series they may traverse sedimentary formations, and some change may be expected. For reasons too elaborate for this paper, I anticipate that this will not occur short of at least 1500 ft. in depth. Besides, veins which, like the Bonanza, probably pass into the rhyolite mass, may traverse it to such depth that the base of the andesite may not figure seriously in the future of their mines. The vein system is strongly developed in the extrusive andesite on both sides of the Pis Pis district, but from the fact that mines have not been opened on it beyond the district (except in far-distant localities), I presume that it carries much less gold. This suggests to me that the gold is not so much due to the extrusive

andesite as to the intrusive rock present in the district; and carried further, I arrive at the pyrite-impregnated rhyolite as the probable source of the gold. It may be present at depth under the Siempre Viva mine.

Near the surface the sulphides are generally thoroughly oxidized to limonite, with irregularly distributed pyromorphite, cerussite, and malachite in small amounts. The gold which was associated with the sulphides chiefly (hard white quartz is practically barren) is then freed and may be seen in the pan as very fine grains. As a general rule the most porous rock is the richest. In the southwestern group, the hematite remains unchanged to near the surface. Very close to the surface the thoroughly decomposed wall-rocks fail to support the vein, and it falls to pieces of quartz imbedded in red clay, forming the so-called *manta*. This works down neighboring slopes and may form an irregular sheet from 2 to 10 ft. thick. The Bonanza mine has the strongest development of *manta* because the vein outcrops on the crest of a low broad ridge. Where the slope is very steep, as at the Lone Star mine, there is no workable *manta*. Most of the mines have worked some *manta*, but much more of the vein in place. The mines pass rather rapidly from the oxidized to the unoxidized zone, there being no strongly marked zone of mixed sulphides and secondary oxidized minerals. To this I must make the exception that certain compact portions of the veins may remain unoxidized to the surface. At the Bonanza mine sulphide ore appears at a number of places in hard compact portions of the vein within 30 ft. of the surface as it was before mining began. Some oxidation may extend down along seams to a depth of 100 ft., but I believe the bulk of the vein is unoxidized at 50 ft. from the nearest point on the surface, or say 100 ft. from the outcrop. In the Neptune vein sulphide ore occurs in places practically at the surface, and the oxidized zone is probably nowhere deep enough to be seriously considered. The Mars mine is not developed to the sulphide zone proper, but bunches of unoxidized ore occur within 50 to 75 ft. of the surface. The Lone Star mine has hundreds of feet of adits in the sulphide zone. In disregard of its outcrop high above neighboring creeks, and the relatively high sulphide content favoring oxidation, the zone of oxidation probably nowhere extends more than 100 ft. from the nearest point on the surface and the weathering of the country rock to a not much greater depth. At the big vein at the Constancia mine, outcropping on the crest of a high ridge, sulphides are appearing in bunches at 160 ft., and on the La Leticia vein only sulphide ore comes from the bottom of a shaft 100 ft. deep. The zone of oxidation in the Siempre Viva vein along the 2300-ft. length developed in the Siempre Viva mine, extends down 50 to 200 ft., generally 100 to 150 ft. The Concordia mine, on the same vein, had not reached sulphides at 60 ft. At the Trinidad mine, also on the Siempre Viva vein, the zone of oxidation extends from 75 to 150 ft. deep.

These observations prove beyond doubt that nowhere in the district does the zone of oxidation extend very deep, rarely to 200 ft.; probably 100 ft. would be near an average. The humidity of the climate and the protection afforded by the stiff clay covering are the reasons for this shallow depth of oxidation. Hence, any proposed extensive mining operations must take the sulphide ore into immediate consideration, and milling plants should be planned on this basis.

The question of the tenor of the sulphide ore is interesting the mine-owners. Its importance lies in the fact that the grade of the oxidized ore at most of the mines is so low that, in view of the probable lower extraction and increased cost of working, any considerable decrease in the average content of the ore in passing from the oxidized to the unoxidized zone would be fatal to the future profitable operation of the mines. In fact, at several of the important mines the end of the oxidized ore is in sight, and the managers realize that they are approaching the time when they must face the problem of working the sulphide ore; hence, they have given some thought to the subject

and have some impressions. As I have reason to believe that one of these managers will shortly treat this subject at length in a public communication, I will confine myself to the remark that after due consideration of all the expressed opinions, statements of assays in various places, and the result of sampling at the most important mine, I have concluded that the sulphide ore will average as much lower than the oxidized ore as would be expected from the lessening in weight of the former by leaching of the sulphides and other basic minerals except the hematite. The exact percentage of decrease will have to be determined for each vein by elaborate development and sampling. I do not think that it will reach 10% in any important case.

It is not my purpose to give specific and detailed information about the individual mines as mining ventures, but a few brief notes on them will be in order. At the Bonanza mine the vein has been pretty thoroughly exposed along a distance of about 1800 ft. by extensive cuts and several adits. It has a northeast course and has a northwest dip of 45 to 50°. The foot-wall toward the northeast is diorite (?), toward the southwest andesite. The hanging-

INDIANS POLING A PITPAN IN EASTERN NICARAGUA.

wall rock toward the northeast is andesite, toward the southwest rhyolite. The large rhyolite area lies close to the vein on the north. The vein is made up of four large ore lenses varying in length from about 200 to over 500 ft. and in maximum width from 13 to 19 ft., separated by low-grade portions where the vein is narrow. The Neptune vein is entirely in rhyolite, and dips northwestward 35 to 50°. It has the usual lenticular form, the lenses best developed running from 3 to 25 ft. in thickness; they may average between 10 and 15 ft., not all good ore, but all vein quartz and sulphides. The Neptune may be a portion of the Bonanza vein faulted by what I have called the Ribabanes fault.

The southwestern portion of the Mars vein is in rhyolite, is only 3 to 5 ft. thick, dips northwest 30 to 60°, and although some portions of it assay well, it has not been mined to any important extent. Near the point where extrusive angite-andesite appears in the hanging wall, the vein rapidly thickens to about 15 ft., and thence northeastward it is one of the large veins of the district and has been extensively mined in open cuts. It continues to have an andesite hanging wall and rhyolite foot-wall nearly to the point where it splits into two large branches, of which the right-hand branch is 10 to 15 ft. thick. The two branches probably rejoin at about the summit of Mars peak, forming a vein 25 to 35 ft. thick horizontally. This part has andesite and rhyolite so mixed in both walls that I have concluded that the country is mainly andesite, abounding in small rhyolite dikes. The dip of the vein here is 70°. Not all of the quartz is ore, but large bodies of it reach a fair milling grade. It is my impression that the unoxidized ore will have a smaller percentage of and simpler sulphides than any other important mine in the district.

The Venus is a strong vein, of which the outcrop has produced a sharp ridge leading to one of the highest peaks of the district. The lenses may reach a thickness of 10

to 15 ft. normal to the dip, which is 70° northward. The vein has not been worked, but is interesting from the fact that it passes from the intrusive augite-andesite into the rhyolite without any change in the gold content.

The Lone Star mine has two veins, which are developed by a number of adits aggregating several thousand feet. The Lone Star vein seems to run from 6 in. to 17 ft. wide (horizontal measurement) and for a considerable distance may be 10 to 15 ft. wide. The profitable ore is in lenticular shoots which have been developed down into the sulphide zone. The Highland Mary vein lies mainly about 100 ft. northwest of the other and is supposed to unite with it at the top of the ridge. The principal working on it is in the centre of a large lens; from an open cut the quartz seems to have been quarried 30 ft. wide for a distance of 200 ft. On No. 6 level the ore is said to be 86 ft. wide in one cross-cut. Both veins are in intrusive augite-andesite.

The Constancia property, all of which is underlain by andesite (aside from the vein quartz), has the large El Vesuvio vein, apparently developed by over 2300 ft. of adits and drifts. It seems to be 30 to 40 ft., and in one place probably 75 ft., wide horizontally. It dips to the northwest 70° . However, mining operations have been carried on chiefly on a group of smaller and richer veins lying north of the big vein. The La Leticia vein averages 3 to 5 ft. wide, with a maximum said to be 14 ft. It is a well defined fissure vein dipping northward about 75° . It seems to abut on and end at the La Constancia vein, workings on which are caved, but which is described as 5 to 6 ft. wide, 500 ft. long, running through a hill 60 ft. high between two creeks and not found beyond them. Several other veins occur on the property.

The Siempre Viva, one of the oldest and best developed mines of the district, is opened on a zone of brecciation 35 or 40 ft. wide, trending northeast and dipping northwest 65° . The hanging wall as exposed in the New adit is a very hard, fine-grained augite-andesite, and the foot-wall rock an extrusive andesite of different appearance. The breccia is cemented by fine-grained quartz and hematite in black grains. This material is said to be nearly barren of gold. It is traversed by veins of quartz which, below the zone of oxidation, are rich in hematite and pyrite, with some chalcopyrite and traces of sphalerite and galena. Quartz stringers come in obliquely from the hanging wall, enlarge in the brecciated zone, and trend with it for hundreds of feet. The quartz seen underground is generally 3 to 5 ft. wide, opening into bulges as much as 15 ft. wide. Going northeastward the vein splits, the left-hand branch pretty certainly going to the Trinidad mine where, with the exception of one place where it is pinched to a mere gouge, it is generally 3 to 5 ft. thick, bulging to 10 ft. in short sections. The vein is said to have some 'coarse gold', but that does not mean grains as large as a pinhead. In the opposite direction, the Siempre Viva vein goes to the Concordia mine, where the quartz is in streaks 3 to 10 and even 15 ft. thick distributed through breccia.

The Hidden Treasure is an old mine on a vein in the rhyolite in the northeastern part of the district. At the Morning Star mine some ore has been milled from a vein 2 to 4 ft. thick (reaching 6 ft. in one place), cutting andesite. Free gold can be seen readily in some of it. At the Panama mine the main vein as exposed in a 120-ft. adit is 6 ft. wide, is of ribbon structure, quartz and sulphides (chiefly galena, with some sphalerite, pyrite, and chalcopyrite). Some layers $\frac{1}{4}$ in. thick are solid sulphides, and the ore, which is andesite, is rather rich in sulphides.

There is a remarkable uniformity of gold content throughout the district. None of the companies mill much ore carrying over \$10 per ton. With careful mining, \$8 ore would probably be a common monthly average. Nearly the whole of such veins as the Bonanza, Lone Star, Highland Mary, La Leticia, and the quartz of the Siempre Viva probably carries at least \$3 to \$5 per ton. This comparative uniformity is related to the uniformly fine-grained character of the gold and its association with widely disseminated fine-grained sulphides. In other words, the ores are not 'pockety,' as the term is commonly used.

The vein quartz will be very hard at depth, that of the northeastern group, except the Lone Star, harder than the Lone Star and the southwestern group. The wall-rock at depth will be hard, the intrusive andesite and certain portions of the extrusive andesite extremely hard. I think these walls will stand well and the mines not require much timber. I expect them not to be unusually wet at depth. In short, the geology of the Pis Pis district is generally favorable to the future of its mines. In fact, it is at present their most favorable feature. The economic conditions—but that's another story, which, I believe, will be discussed at length by an engineer who has lived long in the district.

Tasmanian Gold Mine

The gold mine in Tasmania controlled by John Taylor & Sons is giving disappointing results. The company, called the Tasmania Gold M. Co., was formed in 1903 to acquire properties at Beaconsfield, Tasmania, that had been previously operated by a local company. These mines had been successful gold producers, but owing to the increase of the flow of water in depth, the continued working of the property involved a far greater expenditure on pumping plant than the local owners could afford. This capital was provided on the flotation of the London company, and the plant laid down is one of Henry Davey's best examples of the modern Cornish pump. The water trouble has not, however, been the only drawback, for the lode has proved of irregular content in depth. In 1909 the grade fell seriously, and in October 1910, it was found necessary to reconstruct the company in order to provide new capital. The nominal capital was then reduced from £500,000 to £250,000 by altering the denomination of the shares from £1 to 10s., and the new shares were issued credited with 7s. 6d. paid, thus carrying a liability of 2s. 6d., sufficient to provide £62,500 in cash. The reconstruction of the company was successfully carried through, and one shilling per share has been called up. During the period under review, 53,968 tons of ore was raised, from which 23,143 oz. gold was recovered, realizing £97,820. The expenditure at the mine and in England amounted to £101,913, leaving a loss of £4020. The development work has been actively carried on at the deeper levels, especially on the 1370-ft. level east. The results have not been altogether satisfactory, owing to the presence of a horse of country rock. The shaft tapping the lower levels has been sunk to 1530 ft., and a drift is being started at 1500 ft. The results here obtained will determine the future of the company. The ore reserve above the 1370-ft. level is estimated at 43,084 tons, in addition to which 27,228 tons is 'partly developed,' and 30,000 tons is 'probable.' The company has never paid any dividends up to the present.

Porcupine Development

The cross-cuts from the 200-ft. station of the Porcupine Gold Mines Co. have intersected No. 2 and 3 veins. Up to January 15 about 100 ft. of driving had been done on No. 2 vein on the 200-ft. level. The installation of the 10-drill compressor and the 40-hp. hoist mentioned in the report of November 6 have been completed. Mill machinery should begin to be delivered at the mine soon after the middle of February, and it is hoped that it will be erected and in operation soon after April 1. The mill is being constructed by the Canada Foundry Co., Ltd., under a guaranteed minimum capacity of 100 tons per day. It is expected that this tonnage will be considerably exceeded. The railway is completed to within one-half mile of the district.

Miners in southern British Columbia will petition the Government to establish an assay office and a gold buying station at Trail. They say that several thousand dollars per year could be saved to miners, which is now being paid in express charges to distant assay offices.

Putu Placers

By AN OCCASIONAL CORRESPONDENT

If you are starting to Putú, land at Valparaiso, Chile, take the train to Santiago and from there to Talca. Here a branch line starts for Constitución. From Valparaiso to Santiago is four hours, and from Santiago to Talca is five hours, and from Talca to Constitución is four hours. The connections are not close, hours being lost at each point. From San Francisco to Panama by way of New Orleans requires nine days, and from Panama to Valparaiso requires from fifteen to twenty days, depending on steamer connections.

Gold was found at Putú in 1911 and created excitement all up and down the West Coast. The first gold found was in a boulder bedded in an old foundation—how old,

viction is forced upon them that it is really gold, the price has reached about \$40 per ounce, with eager buyers. There are no other mines in the neighborhood and no placer ground close, though within fifty miles there are several of both. The country is attractive, so far as prospecting is concerned, the hills being red with iron and the country rock being soft, nearly vertical slate, cut with parallel and transverse stringers of quartz. Several high cliffs of slate along the road from Constitución to Putú (a two-hour canter) indicate that it is a 'likely' gold country, if that means anything.

Before the shares of the new company of prospectors were printed, they were being speculated with on the Exchange. The shares have a par value of \$200, and as I left Santiago they had dropped to \$100, due to the easy discouragement of the members of the farming community where the float was found. If the vein has really been found, some will be sorry. The new company will have

TRANSPORTATION AS IT IS NOW.
WORK OF THE PUTUEÑOS.

ON THE WAY TO PUTÚ.
LANDING AT CONSTITUCIÓN.

no one knows. Some say it was buried there to hide it from the early Spaniards, some say it was found on an ancient sea beach, and others say the gold grew right there in the rock after it was placed in the foundation. The finder of the boulder told others, so the population of the entire town stampeded to find more. They found it. The conservative estimate made last fall places the amount at \$100,000. The first locator was Sr. Rodriguez. He and his friends formed a prospecting company and began looking for the vein. They found it after barely two weeks search.

I visited the place among the first, expecting to sell some machinery, but if all the rock found contains 50 to 90% of gold, machinery will be at a discount. One of the members of the original prospecting company wanted to know what kind of machinery I recommended, after seeing the ore, and after I explained that not much machinery was required beyond a melting pot, he insisted that machinery was used in California, Alaska, and South Africa to get the rock off the gold, and would I kindly tell him how they were to get this rock off if they did not use machinery? They also wanted to know what system was used in the states to prevent thefts of gold.

At first the specimens were sold at much less than their value in weight of gold, the local people feeling not certain that they were really selling gold. Now that the con-

plenty of water-power or wood fuel, as they prefer. The prospector for more mines will find ideal climatic conditions, reasonable food prices, cheap labor (60c. per day), and plenty of grass for the burro. Many small prospecting parties are in the field, and as Chileans lean more toward agriculture than mining, the foreigner will probably be the first and most successful in the field. It is a long way to come to prospect. The traveling expenses one way from New York to Putú will not be far short of \$500. And with labor at the price it is, there is no opportunity to go to work after using up the grubstake. Chileans appreciate Americans above their true worth, so personal relations will always be pleasant; and Chileans can be compared in every way with American, English, or French, so don't think you are coming among savages that still wear feathers.

THE board of the Mining Companies Association of southern Russia states that coal mined in the Don basin for the first seven months of 1911 aggregated 1,647,000 tons of anthracite and 10,332,000 tons of bituminous.

ASBESTOS was mined in 1910 only in the four mines of the First Siberian Association, situated in the Angara mining district, the production amounting to about 33 tons, which was sold at \$93 per ton at the mines.

High-Duty Gravity Stamps

By H. STADLER

"The primitive structure of gravity stamps, their clumsy appearance, contrasted with a compact and sweet-running dynamo, has been a perpetual temptation to the mechanical engineer to replace them by some more ingenious machinery. While all new appliances invented for the purpose have so far ended on the scrap heap, even before the 'puffs' proclaiming 'the passing of the stamp' had made the rounds of the press, the stamp still shows a vigorous vitality readily explained by the following considerations:

1. The countless alternations of stresses, inevitably produced in breaking hard rock, loosens all the parts of complicated machinery in time, and only the toughest and bulkiest materials can stand the destructive effect of resilience in the long run.

2. The great adaptability of the stamp to varying working conditions and its range of duty, especially with regard to size of feed. It is helped in this direction by a most satisfactory automatic feeder, a 'thinking' mechanical device which regulates the feed according to the digestion of the stamp.

TABLE I

Distribution of Gold contents over Grades in Battery pulps.

		100%		100%	

3. Its 'life' is practically unlimited, as all its parts can continuously be replaced by repairs made by mine workmen.

4. Crushing by impact, as done by stamps, is extremely well suited for freeing the metallic gold and pyrite from their gangue. The enrichment of the finer grades in gold content, as illustrated by the following figures, explains the great amenability of battery pulps to amalgamation.

In an appreciation of the undoubted merits of the Nissen stamp it is to be regretted that it has not been given a more thorough test. The summary of the 'exhaustive' tests carried out at the City Deep, Ltd., by the Central Mining & Investment Corporation, Ltd., consists of but a few picked tests made under working conditions, which vary just enough to allow a correct conclusion to be drawn as to the effect of these variations. My method of computing crushing efficiency, as practised during the last three years in the experimental work carried out on behalf of the Mines Trials Committee, has been proved to give highly satisfactory and reliable results, and it is therefore gratifying to me to have it confirmed by H. S. Ball,¹ who tells us that after careful examination "it was unanimously decided that this method would be applied to all crushing tests of the McGill University." However, here in Johannesburg, the Central Mining & Investment Corporation, Ltd., which contributes to the costs of the Mines Trials Committee, and is largely represented in that body, seems to give a too liberal interpretation to the maxim of the Lord, not to let your right hand know what your left does. In order to make the data of the summary of Mr. Nissen's paper more legible, the gradings have been replaced by the one representative figure of their mechanical value, and the three factors determining the energy invested in the stamps by the one value of foot-pounds per second.

^{*}Author's revised copy of paper printed in *The South African Mining Journal*, December 2, 1911.

¹"The Economics of Tube Milling," Bull. Inst. Min. & Met., August 30, 1911; *Mining and Scientific Press*, September 23, 1911.

The mechanical values of the gradings are practically identical for both types of stamps and exactly correspond to those of the curve established for varying coarseness of battery mesh. This confirms the statement made in 1909² (referring to lighter stamps) that the gradings of screen pulps are not materially affected by varying working conditions of stamps, but are practically exclusively determined by the mesh aperture, and it shows that the principle also holds good for heavy stamps, at least within the range of the coarse meshes used in the above tests. The horse-power consumption has been calculated from the value of the foot-pounds per second, with an allowance of 25% for loss in friction (in an old mill 30% is nearer the truth). By this method the power consumption works out lower, in all tests, for the ordinary stamps, while the table of the Central Mining & Investment Corporation, Ltd., with one ex-

ception, gives lower values for the Nissen stamp. Since the mechanical arrangements for lifting the stamps are practically the same in both types, the horse-power (as theoretically established) must be taken as giving more correct relative values than those obtainable by unreliable direct measurements. A possible error made by taking exactly the same height of drop for both cases would be in favor of the Nissen stamp, which, being heavier, might have its lift a little increased in consequence of a greater compression of the rock-bed. Until satisfied that all necessary precautions have been taken for exact tonnage measurements, the duties given in the table must be accepted with reserve. In truth, they are in some cases not logically related to one another, nor to the conditions of the individual tests. The greatest drawbacks for such tonnage measurements are the continuous fluctuations in the proportion of 'fines' contained in the feed. From the following complete grading of a battery feed it will be noted that, while the mechanical value of the total feed is 0.424 E.U., or say 0, the + inch portion (about 2₃), taken alone, works out at -3.0 E.U. (the - indicating coarser than the one-inch, or 0 - grade), and the - inch portion at + 7.5 E. U. (Table II).

Assuming as an extreme case that temporarily only the

²Mines Trials Committee, second report of Sub-Committee.

+ one inch portion (about $\frac{2}{3}$ of the total feed) goes to the mill, the work done by the stamps must be credited with three additional energy units (E.U.). On the other hand, if the $\frac{1}{2}$ -inch portion (about $\frac{1}{3}$) is considered alone, 7.5 E.U. should be deducted from the mechanical value of the screen pulp as work already done by the preliminary crushers. Stamps dealing with such a fine feed necessarily, therefore, have a correspondingly increased duty. In the Giesecke mill tests, where exact tonnage and power measurements were possible, it was ascertained that the variations of the percentage of "fines" easily affected the duty by about 2 tons per hour, or 15% of the duty. Without special arrangements and precautions the obtaining of representative average samples of a day's run is practically impossible, and for comparative tests it is just as accurate—or inaccurate, if you like—to assume the feed to be uniform and of the 0 grade.

As stamps under exactly similar conditions do invariably the same class of work, it is more advisable to extend experimental tests over comparatively short periods only.

rigid than in the ordinary 5-stamp mortar boxes, where rocking may take place. The vibrations due to the shocks being shorter, less energy is lost in shaking the building and surroundings.

The lower efficiency shown by the ordinary stamps is partly due to energy lost in deformation within the limits of elasticity, or permanent deformation before reaching the breaking point. To some extent, however, the loss of efficiency is only apparent, as the lower duty is to a certain extent balanced by a larger amount of crushing work performed in the very finest grades as a consequence of the attrition and abrasive action. By taking for the mechanical value of the -200 grade a standard value of 28 E.U., the work done in producing ultra fine slime is not accounted for, but this is quite justified, as, for Rand ore, grinding finer than to 200 mesh is mere waste of energy. From these premises may be made the deduction that the superiority of the Nissen stamp would be still more pronounced when crushing through finer mesh. The policy of ultra fine grinding by wholesale tube-milling, just now in

during which the working conditions can be perfectly controlled and maintained. By making tests in one series for each variable, the use of the regular curve obtained is not only a valuable check, but also the only way to arrive at definite conclusions as to the effect of the variables on crushing efficiency. Allowing for all these uncertainties in the data given, the fact remains that the Nissen stamp shows a decidedly higher efficiency than ordinary stamps.

In contrast to life, which is created by life, but doomed to pass away into spheres hitherto inaccessible to human research, matter and energy can neither be produced nor destroyed, but only converted. Theoretically, no efficient machines exist, and what we call in practice efficiency is only the relative amount of useful work done with regard to the special purpose for which the machine has been designed. With this reserve the greater efficiency of the Nissen stamp, or the relative loss of energy in the old stamps, may be explained as follows:

1. The roundish shape of the particles leaving a 5-stamp battery proves that a certain amount of the reduction work is done by attrition and abrasion during the shifting and knocking about of the particles in the mortar box. In the one-unit Nissen stamp the particles are less subject to this action and less energy is lost by useless water churning.

2. The radial arrangement of the screen allows an immediate rejection of the already finished product, leaving behind a clean material, which, since an ample percentage of its apparent volume is free interstices, is not subject to cushioning.

3. The accumulated energy at the moment of the impact of a falling stamp is not only distributed over the surface area of the shoe, but it is also transmitted in depth. With a too thick or uneven rock bed, the amount of energy absorbed in packing the material, before crushing by compression can take place, may be so great that the crushing work done by direct impact becomes almost nil. The maintenance of an even surface of shoes and dies and the facility for weighing the shoes as they wear, are far-reaching factors of inefficiency hitherto beyond our control.

4. The blows of a one-unit Nissen stamp are bound to be harder and shorter, as the mass of the anvil formed by the thick and heavy bottom of the mortar box, placed in the centre of the foundation, is certainly more solid and

fashion in the metallurgical department controlling the Rand Mines, has been, unfortunately, no inducement to them to extend their 'exhaustive' tests in this direction, and the Nissen stamp has therefore not been given the chance of demonstrating its great possibilities as a fine grinder.

Heartly thanks are due to P. N. Nissen for his able and interesting paper, which, I think, leaves on all the impression that this stamp marks a great and real progress in stamp-milling. The new departures are based on sound and theoretically correct principles, and the details of the mechanical arrangements are practical and handy. This is confirmed by the best judges of new inventions in this connection—by the shiftmen, the men who have to work with it. The calculations of comparative working costs and capital expenditure may be open to criticism, but, compared with the other great advantages claimed and proved, the differences are too small to justify protracted squabbling about the matter.

Cultivating Dredged Areas

In further proof that the ill-effects of dredging operations have been greatly exaggerated, as had been already shown by the successful culture of black-wattle and other trees on the ground which had been declared ruined, J. D. Bromley, dredgemaster, of Harrietteville, near Bright (V.), has succeeded in raising magnificent crops of grass and clover on similar ground. Mr. Bromley tried a variety of seeds in order to decide which crop gave the greatest guarantee of successful results. In several cases, the results have surpassed all expectations, and the general result goes to show that if, instead of appealing to the Minister of Mines to restrict the work of gold-winning, on which the previous prosperity of the Bright district was founded, the farmers would put their shoulders to the wheel, they might even be the gainers through being driven to reclaim the land. The grasses which gave the best returns were *paspalum* and cow-grass; the latter grew to a height of 2 ft.; red clover also gave excellent results, and it is said that during the recent hot weather, Mr. Bromley's crops stood out in marked contrast to those around them, as well as in other parts of the country. *Australian Mining Standard*.

The Wisconsin Zinc District

By P. K. KELLEY

PRODUCTION

A striking increase in production from the Wisconsin zinc district is evidenced by the figures for 1911 compiled by J. E. Kennedy. The tonnage sent to the smelters was 75,000, as against only 63,000 for 1910, an increase of almost 20 per cent.

In the Missouri-Kansas district, which is the principal producer of high-grade zinc ore, there was a decrease in 1911 of 28,000 tons from the production of 1910. When this is considered, it is indicative of the excellent condition of the Wisconsin district that its production has shown an increase of 12,000 tons in the same period. These favorable statistics are more remarkable in the face of the numerous fires that have visited the district. Several mining plants have been totally destroyed by fire, but the loss of two of the important separating works has had the most serious effect upon operations of the district as a whole. In addition to the separating plants that were destroyed by fire, the mills at the Minnie, Mound City, and Coker mines, and one of the Kennedy mills were burned.

An impressive fact regarding Wisconsin zinc-ore production is that the average assay of concentrate shipped in 1911 was 34.68% zinc. In 1910 this average was 37.52%. Two inferences can be drawn from this comparison. One is that cost of producing ores has been lowered so that a lower-grade concentrate can be put on the market at a profit. The other is that mines producing ore assaying under 36% have contributed more to the increase of production than have those properties turning out ores of higher grade.

The following table shows total shipments of zinc ore in 1910 and 1911 by towns, excepting shipments from separating plants direct to smelters.

Town.	1910. Cars.	1911. Tons.
Highland	215	4,457
Linden	164	8,184
Harker	154	4,173
Mineral Point	82	1,173
Montfort	44	1,790
Livingston	226	6,483
Rewey	74	2,851
Platteville	461	14,684
Cuba City	185	2,201
Benton	618	25,466
Hazel Green	384	20,121
Shullsburg	42	4,705
Galena	257	10,766
Dodgeville	9	200
Dubuque	5

	1910.	1911.	Increase.	Decrease.
Production zinc ore, tons	102,070	107,187	5,117
Surplus in bins (Est.)	24,000	29,000	5,000
Net increase in zinc ore	10,117
Total shipments of lead, pounds	11,276,265	9,002,025	2,274,240
Total shipments of pyrite, pounds	28,122,850	28,679,030	556,180

OPERATION

Facilities for handling zinc ores have been greatly increased in the year just past. The Mineral Point Zinc Co. has increased its roasting capacity by rearranging the plant

MAP SHOWING RELATION OF WISCONSIN DISTRICT TO COALFIELDS AND SMELTERS.

at Mineral Point. More important, however, is the completion of the new zinc oxide works. Several hundred thousand dollars have been spent in making this the largest single ore-treating plant in the district. For manufacturing oxide they operate four blocks of 12 furnaces each and treat daily 90 tons of ore. Electrical automatic machinery, cranes, conveyors, hoists, mixers, and trams have been introduced. At Cuba City the Campbell Separating Co., after running an experimental plant for two years, has completed a roasting and separating works, which has a daily capacity of 100 tons. The process is unique as well as important. The ores are subjected to

only a slight roast, and, in addition to making a high-grade zinc product, pyrite is saved as a by-product that is useful in making sulphuric acid. A Mathey roaster, handling 40 tons per day, was put in operation at Benton by the Wisconsin Separating Co. At the Lucky Twelve mine a Mathey roaster was erected, and the two kilns at the mills and the one at the Murphy mine were again started. At Platteville the Wisconsin Zinc Co. is at present making additions to the roasting equipment at the Empire mine. In addition to plants built for roasting and separating purposes, a normal amount of construction work on milling plants was accomplished. The Minnie and Coker mills, which were burned during the year, have been rebuilt on a much larger scale and have resumed shipments. Besides these, the Wallace, Dodger, Homestead, Murray, Fox, Winskell, Cleveland, Wilkinson, Rowley, and Merry Widow have completed new mills.

MARKET CONDITIONS

The year opened with the price of 60% ore at \$42 and spelter at 5.35c. The ore market held at about that figure until nearly April, when the price dropped slightly below

the market for the high-grade ores. The smelting capacity throughout the country is rapidly being increased, and before the year is half over the new smelters, and those with increased capacity, will be in need of much greater tonnages than are now being purchased. This increased demand for smelting ores should have its good effect on the ore market. There is every reason to believe that the year 1912 will be one of satisfactory ore prices.

NEEDS OF DISTRICT

Prospecting by drill has not been carried on for several years with the impetus that it deserves. The district includes an area extending north and south over 50 miles, and east and west 35 miles, a total of more than 1,000,000 acres of land, much of which is favorable for prospecting. Why is this enormous area allowed to go unprospected? The fault lies with both the operators and the land-owners. The former hesitate to undertake prospecting a lease that has no surface indications of ore. Operators prefer to proceed with a property upon which a certain amount of preliminary work has been done. How then can the land-owner, whose land has never been prospected, interest com-

\$40 and hovered around that point until June. Then it started to climb gradually, and by September had reached \$44. In November the high price of \$46 was reached, and the year closed with ore selling for \$44. The price of spelter weakened slightly after the first of the year, but regained its strength in February. The market suffered another slight fall in April which continued well into June. A steady increase in this metal set in at the middle of the summer, and by October spelter was selling at St. Louis for 6c. per pound. From this point the price kept mounting until 6.90c., St. Louis, was reached. At this point the market had a sudden slump and the price fell to 6.20c. within a week. It remained about 6.20c. for about two weeks, and the year closed strong at 6.25c. per pound.

OUTLOOK

Everything points to a good year in 1912. The American Zinc Ore Separating Co. will probably rebuild its separator either in this district or in southern Illinois. The Joplin Separating Co. will have its new plant completed by March 1 with an added capacity of 40 tons per day. The National Zinc Separating Co., a subsidiary of the Vinegar Hill Zinc Co., has broken ground for a roasting and separating plant near Cuba City which will start with a capacity of 60 tons daily. There is every indication of a continued increase in tonnage. Several new mines are being opened, and concentrating mills will be built. A number of mines, practically non-producing in 1911, are now prepared to make weekly returns. It has been necessary of late to restrict the amount of output at some properties, but, with the new separators operating, production will again be brought to a maximum. It is probable that the smelters will shortly be more actively in
